Progress.—By November 1st, 1930, the condition had become worse, and during the past few weeks patient had only managed to walk about her room with great difficulty. Intention tremor was present on both sides, and the arms were now spastic. Abdominal reflexes not elicited. Legs very spastic, and vibration sense absent in both legs. Urgency of micturition continuous, with occasional incontinence. Patient was instructed to take half a pound daily of lightly cooked liver. Medicinal treatment otherwise was discontinued. After six weeks of liver therapy patient's condition began to improve noticeably, and she was able to get about more easily. The urgency of micturition disappeared. In three months' time the legs were less spastic and vibration sense had returned, although the plantar responses were still extensor and the abdominal reflexes absent. Nystagmus was now more difficult to elicit, and the intention tremor less marked.

CASE V

T.; male, aged 47. Admitted to Royal Infirmary on March 9th, 1931.

History.—Since the age of 20 the patient has had numbness in his left arm and leg, with a varying degree of weakness. During the last three years the power in the left arm has been poor, and for a similar period his left hand has been very shaky. During the past year he has been unsteady in walking, and for some weeks before admission was unable to stand. The legs were stiff, and frequently went into spasm. Urgency of micturition has varied in intensity. There have been no eye symptoms. At one period, when he was in bed for fourteen days with a bursitis, both legs became much stiffer.

Examination.—On March 9th, 1931, there was marked lateral nystagmus in both eyes. Discs healthy. Extreme intention tremor on left side, slight on right. Complete astereognosis in left hand. Left arm and leg weaker and more spastic than right. Abdominal reflexes absent. Both plantar responses extensor. Generalized delayed sensation in left arm and left leg. Cerebro-spinal fluid entirely negative to the Wassermann, colloidal gold, and globulin tests.

Progress.—Patient commenced liver diet on admission, and his condition began to improve almost immediately. On April 8th, 1931, he was able to walk easily without a stick, and helped with the ward work. The tremors were much less marked, the nystagmus was less marked, but extensor responses were still present and the abdominal reflexes still absent.

Disseminated sclerosis is notoriously a difficult disease in which to assess progress. It would, however, be remarkable if all of five consecutive cases should show spontaneous remissions to an extent which is beyond our previous experience of the disease. Moreover, it is unusual to find natural remissions in disseminated sclerosis in the colder months of the year. Our experience of later patients appears to confirm the favourable results obtained in the five cases now reported, but the time they have been under treatment is not sufficient to permit of maximum improvement.

We submit that we have at least presented a case for inquiry and trial, and it seems probable that, as in pernicious anaemia, it may be no longer necessary to search for an unknown organism to explain a disease of unknown etiology. It is further possible that the etiology may be explained in terms of a food factor deficiency.

SUMMARY

1. We record five consecutive cases of disseminated sclerosis of varying duration and severity, treated with whole liver with remarkable improvement.

2. Two of these patients, previously totally unfit, have returned to work, as a mechanic and a farm hand. One man unable to stand is now walking briskly. One woman who could walk only with assistance can now walk well. One young woman who had given up games for two years can now play hockey.

3. Promising results have been obtained in later cases of too short duration to justify record.

4. It is suggested that disseminated sclerosis may form an addition to the list of deficiency diseases.

WOOD'S GLASS IN THE DIAGNOSIS OF RINGWORM

BY

JOHN KINNEAR, M.D., M.R.C.P.ED.

ASSISTANT PHYSICIAN FOR DISEASES OF THE SKIN, DUNDEE ROYAL INFIRMARY

It is now nearly six years since Margarot and Deveze[1] drew attention to the fluorescence of hairs infected by ringworm in light filtered through glass containing nickel oxide, known as Wood's glass. They differentiated between the fluorescence of microsporon and trichophyton infections, and laid the foundation of a diagnostic method of very great value to those who have to deal with this disease. I have used Wood's glass in hospital, school clinic, and private practice since the autumn of 1927, and, though I believe it is indispensable for such work, I have found that it has very definite limitations, which do not seem to have been stated with sufficient clearness in the literature.

PHYSICAL PROPERTIES OF WOOD'S GLASS

This glass was first described by Professor R. W. Wood of Johns Hopkins University, but a similar glass was discovered independently in this country. If, by means of an ordinary glass prism, the beam of light from a carbon arc be split up after passing through Wood's glass and the resulting spectrum thrown on a white screen, it will show a narrow band of red and a broader band of violet light. If this screen is replaced by a sheet of paper coated with vaseline, a bright band of bluish fluorescence will be seen just outside the violet end of the spectrum, a narrow band of comparative darkness separating this fluorescing portion from the band of violet light. Hairs infected by *Microsporon audouini* show the same phenomenon ; they fluoresce only when held opposite this part of the spectrum. During various experiments, microscopical and macroscopical, it was obvious that ordinary soda glass was transparent to the rays causing this fluorescence, and on application to the makers I was not surprised to learn that it was soda glass containing nickel oxide. Thus, in choosing the source of light for use with this glass, attention need be paid only to intensity of light (an important factor, as the glass is very dense and allows only a small amount of light through) and to convenience, as any ordinary source of white light produces the long ultra-violet rays necessary to give the fluorescence. I have demonstrated the fluorescence of ringworm hairs, although dimly, using an ordinary gas-filled electric bulb, but I prefer a small carbon arc lamp, such as is used in a "magic lantern." This apparatus, without its lenses, has been found very useful, both in the examination of heads and in microscopical work with Wood's glass, the glass being placed in the slide carrier, and hairs examined with great ease in this light or in ordinary light by moving the slide carrier, interposing the Wood's glass at will. It should be noted that this glass is very brittle when exposed to heat, and cracks easily, especially if irregularly heated. Margarot and Deveze[2] have implied that a mercury vapour lamp is necessary for this method, but Roxburgh[3] states that a small carbon arc is also a suitable source of light. I agree with other observers that total darkness is not necessary or even desirable, especially if several children have to be examined. A little light is not a hindrance to the recognition of the fluorescence, and allows of easy movement of the patients and also of their parents, whom I encourage to be present. The demonstration of this fluorescence is a salutary object lesson to parents who are reluctant to realize that there is much wrong and that epilation is necessary.

RINGWORM OF THE SCALP

The results obtained with the different types of fungus responsible for ringworm of the scalp vary so greatly that they must be considered separately. It must be noted that attention should be given only to the presence or absence of fluorescence in the hairs themselves. Any scaly condition of the scalp may give a fluorescence indistinguishable from that due to ringworm infection of the skin, and, conversely, infected hairs may be seen fluorescing in a non-scaly, non-fluorescing scalp. It is only necessary for the scales to be removed, say, by washing, for this to occur. The fact that any scales may fluoresce is due to the fluorescent properties of keratin itself. Clinically this is best seen in the nails, which are almost pure keratin ; they show a white fluorescence, but the fluorescence of a scaly skin is much less than that of hairs infected by ringworm.

Microsporon Infections

With regard to infection by *M. audouini* I agree entirely with other investigators. The brilliant green fluorescence of the affected hairs is characteristic and unmistakable. I have never found an infected head on which the hairs did not fluoresce, nor have I seen a hair fluoresce in this way which on microscopical examination proved to be uninfected.

One fact which this method has brought to light is that slight infections of the scalp can easily be overlooked on naked-eye examination. There may be, especially in long-standing cases where the infection is attenuated, no scaliness of the scalp, and the hairs may be unbroken ; the infection of the hair is not sufficiently intense to render it brittle, yet, as soon as the light from Wood's glass is thrown on such a head, individual hairs, often several inches long, are seen to stand out like lighthouses, and if these hairs are epilated and examined in liquor potassae under the microscope, the infection is invariably confirmed. This has been brought to my notice especially after epilation by thallium acetate. Thallium epilation is not so complete as that following the application of *x* rays, and several times it has been found that a case which clinically showed no evidence of infection after thallium treatment still showed several fluorescing hairs scattered through the scalp. I now accept no case of ringworm of the scalp due to *M. audouini* as cured until examination with Wood's glass shows no fluorescing hairs. On the other hand, it is very easy by means of Wood's glass to prove that a child is free from this infection—a proof which is practically impossible to obtain by any other method. This is a point of great practical importance, and one on which the user need have no dubiety.

The striking results obtained with *M. audouini* led me to conclude that if the hair did not fluoresce, microsporon infection could definitely be excluded. I was surprised, therefore, when a child's hair obviously with a microsporon infection failed to show any fluorescence with Wood's glass. Microscopical examination of the hairs in liquor potassae, however, confirmed the diagnosis of microsporon infection, and on examining epilated hairs under the light from Wood's glass the lower ends—that is, the intrafollicular portions—were seen to fluoresce, though less than in the case of hairs infected by *M. audouini*. Microscopically the whole length of the hair was infected, and under Wood's glass the fluorescence was seen gradually to disappear, whereas in *M. audouini* infection the fluorescence remains indefinitely in liquor potassae, and is coextensive with the infection. I have in my possession hairs infected by *M. audouini* cleared in liquor potassae and mounted in glycerin over a year ago which are still fluorescent. On culture on Sabouraud's medium this

fungus was found to differ distinctly from *M. audouini*; it has not so far been identified, and no other case of infection by this microsporon has come to my notice. I mention this case merely to point out that infection of the scalp by microspora other than *M. audouini* may not show the same fluorescence, and thus lead to error. The occurrence of such infection is, of course, very rare in this country.

Trichophyton endothrix

It has been stated that hairs infected by trichophyton exhibit less fluorescence than those infected by microsporon, but still show a characteristic reaction. This view is upheld by Margarot and Deveze[1 2] and by N. Gray Hill[1 3]. I have seen many cases of infection by *T. endothrix*. On culture, *T. crateriforme*, *T. acuminatum*, *T. sulphureum*, and a fourth variety showing polygonal craters (? *T. polygonum*) were found to be responsible. In no case was there any demonstrable fluorescence due to infection of the hairs. In one or two cases a pale white fluorescence of a few hairs has been observed, which seems to correspond to the fluorescence described by other authors. On microscopical examination of these hairs they were seen to be surrounded by a sheath of epithelial cells, evidently an exfoliation of the lining of the hair follicle; if this sheath was removed all fluorescence ceased though the hair was badly infected. A similar phenomenon (described later) was also observed in heads free of ringworm. The scalp in a trichophyton infection is scaly, especially round the orifices of the hair follicles, and little points of fluorescence corresponding to these orifices may be seen. This condition also occurs in diseases other than ringworm. In several cases I have seen heads obviously infected by trichophyton in which there has not been any sign of fluorescence, even of scales. Even if hairs infected by trichophyton did fluoresce, they are frequently found twisted up under the scales, and such fluorescence would not be visible.

Fluorescence in heads infected by *T. endothrix* is therefore inconstant; it is not due directly to the infection of the hairs, as in infection by *M. audouini*, and cannot be relied upon either for diagnosis or for estimation of cure.

Trichophyton ectothrix

I have examined about a dozen cases of kerion of the scalp and beard, and in each case *T. asteroides* was the parasite responsible. In no case were fluorescing hairs found; but the clinical diagnosis of kerion is easy, its extent obvious, its duration self-limited, and a cure clinically simple to ascertain. The necessity for a means of diagnosis, such as Wood's glass, is not nearly so great as in the other varieties of ringworm.

Favus

Infection of the scalp by *Achorion schönleini* is usually easy to recognize, since the typical scutula are unmistakable. Sometimes, however, where a head has been well kept and is free from scutula, and thus the typical alopecia not allowed to develop, the diagnosis may be very difficult, the favus closely simulating a chronic dermatitis of the scalp. Wood's glass is of definite value in such cases.

If a scalp infected by favus is examined with Wood's glass it will be noticed that tufts of hair to a greater or less extent, according to the degree of the infection, show a pale white fluorescence, much weaker than in microsporon infection. These tufts of hair will be seen to correspond to the areas of dull lustreless hair typical of this condition. If such hairs are examined under the microscope in liquor potassae the first thing one notices is that they are full of bubbles of air; mycelium is absent, or scanty, being most profuse towards the base of the hair. The explanation seems to be that the fungus gradually dies out as the hair grows, and leaves the hair a more or less empty cylinder, with loss of its colouring matter; thus the natural fluorescence of the keratin becomes visible. Very fair or white hair also fluoresces for the same reason, but this phenomenon is easily distinguished from that found in favus, in which the tuft-like arrangement cannot be mistaken. I have on one or two occasions diagnosed favus where scutula were absent from the result of examination by Wood's glass alone, and had the diagnosis confirmed afterwards by microscope and culture tube.

WOOD'S GLASS IN OTHER DERMATOSES

I have not found Wood's glass of value in other dermatoses. In ringworm of the body it is not nearly so effective as naked-eye examination; the scales may certainly fluoresce, but in the same manner as in any other scaly affection. Margarot and Deveze,[2] and Goodman[4] give a detailed description of the skin viewed with this glass in a variety of conditions, but the only case in which I have found it of use has been in mild pityriasis simplex of the scalp, where a demonstration of the tiny fluorescent scales to the parent has shown the need of treatment when "dandruff" was not suspected before. I have seen one case of pityriasis simplex of the scalp where not only did the scales on the scalp fluoresce, but a large area of hair on the vertex showed distinct evidence of fluorescence for about half an inch from the base of each hair. There were no broken hairs, and no parasite was found on microscopical examination of the hairs; it seemed as if the pityriasis had affected the lining of the hair follicles, which had been shed as a sheath to the hair. No real difficulty was experienced in excluding ringworm as there was no clinical evidence of its presence beyond scales, and the fluorescence was the pale white of keratin, not the brilliant green of microsporon infection; it is an easy matter to epilate a single fluorescing hair and examine it microscopically. In a case of ichthyosis, besides the usual body lesions, there was a hyperkeratosis of the mouths of the hair follicles, and the scalp was dotted with fluorescent points corresponding to these orifices; again no difficulty was experienced in excluding ringworm.

The presence of vaseline on the scalp is sometimes a difficulty, as its intense blue fluorescence may hide that due to ringworm. Thorough washing with soap and water is all that is necessary to obviate any chance of missing a positive case.

There is great difficulty in arresting the fluorescence of microsporon-infected hairs. I have tried various methods, but have never succeeded in doing more than cause the fluorescence to disappear for an hour or so. The hair soon seems to lose any substance with which it has been coated. This is important from the point of view of the constancy of the results.

EXPLANATION OF THE FLUORESCENCE

Little is known about the production of fluorescence. It appears to be due to the absorption of light of one particular wave-length and its re-emission on another wave-length. Microscopical examination of fluorescing hairs with light filtered through Wood's glass shows that it is the fungus itself which fluoresces. The dissociation of the hair in liquor potassae may be watched, and it can be seen that while the hair with its contained mycelium still glows, so also does the detached sheath of spores. The illumination is too faint to show up a single spore, but where there is a group of even half a dozen a distinct fluorescence will be observed.

I have not been able to confirm the observation of Margarot and Deveze that "cultures on Sabouraud's medium are equally as fluorescent" as microsporon ring-

worm and favus. I have had the opportunity of observing over forty different varieties of ringworm fungi on Sabouraud's medium under the light from Wood's glass, and have been struck by the entire absence of fluorescence from any of them, no matter to which group they belonged. They certainly varied in colour under this light, sometimes yellow or red, usually a dull brown, but it was only when the cultures were quite dried up that any fluorescence was seen.

SUMMARY

Hairs infected by *M. audouini* are brilliantly fluorescent in light filtered through Wood's glass. This fluorescence is characteristic and constant, and is coextensive with the infection. The diagnosis and estimation of cure of this form of ringworm is easy and certain by this means. Hairs infected by other forms of ringworm are, in my opinion, incapable of detection by this method with any certainty.

Hairs affected by favus give a faint fluorescence. Wood's glass is of value in aiding the diagnosis of this condition.

Almost any scaly condition of the skin will give a fluorescence; attention should therefore be paid only to the presence or absence of fluorescing hairs in the detection of ringworm of the scalp. I have not been able to arrive at any useful conclusion in the differentiation of other dermatoses by this method.

The fluorescence is due to the presence of *M. audouini* in the hair in the case of microsporon ringworm; in other cases to the fluorescent properties of keratin. Any ordinary white light may serve as a source of illumination, provided it is of sufficient intensity, and ordinary glass does not impede the necessary rays; condensers, etc., may therefore be used without interfering with the phenomenon.

APPENDICEO-CAECAL INTUSSUSCEPTION

BY

E. N. MACDERMOTT, B.Sc., M.D., F.R.C.S.I.

PROFESSOR OF THERAPEUTICS, UNIVERSITY COLLEGE, GALWAY; JUNIOR SURGEON, CENTRAL HOSPITAL, GALWAY

While the apparent rarity of this condition (it is not mentioned in the usual textbooks or in Clubbe's monograph)[1] is alone sufficient to justify a report, there is also a possibility that its occurrence is in reality more frequent than the literature suggests.

CASE HISTORY

A boy aged 8 was admitted late at night to the Central Hospital. No historical data were sent. He appeared comfortable and fell asleep before I saw him; the temperature was 98·3° F., pulse 88. Next morning he complained of pain in the right iliac fossa. His bowels had acted. Temperature 98·6°, pulse 92. The abdomen moved freely with respiration and there was no definite rigidity or tenderness; accurate palpation was impossible, as the child cried. Four hours later the temperature was 99° and the pulse 88. There was marked hypertonus in the right iliac fossa; deep palpation now demonstrated just above McBurney's point a mass about the size of a walnut, freely movable, slightly tender and dull on percussion. A diagnosis of appendicular abscess or early intussusception was made. The abdomen was opened immediately by Kuttner's incision, and the caecum delivered. It was observed that two-thirds of the appendix was invaginated into the caecum, and the remaining portion, which protruded, was reddened and obviously inflamed. An attempt to reduce the intussusception succeeded in delivering a further third. The effort was then abandoned, as the adhesions between the two viscera were too dense to be broken down safely. A clamp was applied above the apex of the intussusception, the meso-appendix was ligatured and divided, an incision was made at the junction of ensheathing and entering layers, and the appendix, with the head of the caecum, was removed. The caecum was closed with two layers of sutures, and the abdomen was stitched up without drainage. Convalescence was uneventful.

The doctor who had first seen the case stated that the child was ill for fourteen days with "bloody diarrhoea," but the parents refused to allow his removal to hospital; he also said he suspected intussusception. The appearance of the part removed is shown in the accompanying photograph.

Appendix and cuff of caecum, which has been stitched in place by two sutures.

DISCUSSION

Szenes,[2] quoted by Huddy,[3] gives a total of fifty-eight cases of intussusception in the ileo-caecal region, of which nineteen, as well as Huddy's own case, were of this variety; unfortunately, he omitted ten case reports. The division into appendiceal and appendiceo-caecal varieties is, however, not of great moment, as the symptoms are the same, and intussusception of the appendix proper may be secondarily inverted into the caecum. The fairly frequent occurrence of such cases was suggested to me in a personal communication from Sir Thomas Myles, who mentioned that he had operated in two such cases; Mr. O'Connor of Croom had told him of another. The typical clinical course, as described in the literature, is:

1. Pain first around umbilicus, later in right iliac fossa, sometimes also in back; colicky in nature, intermittent; may extend over several months.
2. Vomiting may occur early in attack or may be a late symptom.
3. Reflex constipation, or when intussusception has become congested, diarrhoea with mucus and blood in stools.
4. No rise in temperature or increase of pulse rate until appendix is inflamed.
5. No rigidity unless appendix is inflamed.
6. A palpable tumour usually just above McBurney's point, slightly tender, dull on percussion, and freely movable unless fixed by adhesions.

On considering the musculature around the ileo-caecal junction (the commonest starting-point for intussusception) and comparing it with the arrangement at the base of the appendix, we are struck by the similarity presented—namely, a sphincteric ring, capable of becoming, through spasm, a hard, relatively fixed mass held at the apex of a tube which exhibits peristalsis; we are surprised at the relative infrequency of the condition described above, and are inclined to wonder if recurrent intussusception, spontaneously reduced, may not frequently be the real lesion in many cases which, though presenting

no obvious lesions at laparotomy, are relieved of symptoms by appendectomy. That intussusception occurs and reduces itself, even in the normal abdomen, was strikingly demonstrated in Alvarez's film of intestinal movements, exhibited in Ireland by the Kodak Company two years ago. Additional support is given to this opinion by Myles's unpublished observation of such an invagination of the appendix into the caecum occurring spontaneously and reducing itself with regular rhythm in a patient on whom he was operating for caecal hernia.

Liek[4] and others, on account of the frequent absence of microscopical changes, state that many cases diagnosed as "chronic appendicitis" owe their symptoms to local spasm of neurotic origin, and treat these cases, often successfully, with large doses of atropine. The view expressed above is capable of explaining their results: laparotomy causes the invagination to become reduced, unless it is held in place by adhesions, and so no lesion is found at operation; the atropine relaxes the spasm of the appendix sphincter, thus preventing recurrence of the intussusception, and thereby relieving the patient's symptoms. It has frequently been shown experimentally that simple laparotomy as a rule abolishes all intestinal movements, and therefore it is not surprising that the actual occurrence of such an intussusception has not been oftener observed: if appendectomy were performed under local and splanchnic anaesthesia (which does not inhibit peristalsis) it might be possible to get additional evidence as to the truth of the above explanation.

SUMMARY

1. A case of appendicco-caecal intussusception is described.

2. The clinical history, as found in the literature, is summarized.

3. Evidence is adduced suggesting that the condition is not as rare as would appear from the literature, and that it may be the real lesion in many cases of "chronic appendicitis."

INFARCTION OF THE HEART WITH PERICARDIAL EFFUSION IN A YOUNG PHTHISICAL SUBJECT

BY

T. A. HUGHES, M.D., M.R.C.P.
LIEUTENANT-COLONEL I.M.S.
PROFESSOR OF CLINICAL MEDICINE

AND

MOHAMMAD YUSUF, M.D.
CLINICAL ASSISTANT, MEDICAL COLLEGE, LAHORE

The following report deals with the occurrence, in a young tuberculous subject, of the symptoms and signs of cardiac infarction, with the subsequent development of a pericardial effusion.

A Moslem male, aged 28, was admitted to hospital on August 8th, 1930, with chronic tuberculous disease of both lungs. Constitutional symptoms were severe; there was considerable wasting, and the sputum contained numerous tubercle bacilli. No signs of extrapulmonary tuberculosis were detected, nor was there any evidence of cardiac disease. The patient made good progress until October 6th, by which time the temperature had settled down to normal, and the weight had increased by a stone. Tubercle bacilli were, however, still present in the sputum. On the latter date, about 7 a.m., while resting quietly in bed, the patient suddenly experienced pain of an extremely severe nature all over the cardiac area and under the lower part of the sternum, the position of maximal intensity being just inside the apex. The pain radiated widely—down the inner side of the left arm into the hand, down the right arm as far as the elbow, and down the left side of the body and left leg as far as the knee. It yielded only to large doses of morphine, nitrites having no effect. The patient was very restless, and complained of difficulty in breathing. The possibility of pneumothorax was considered, but there was no sign of this condition. The pulse became very weak and rapid, but was quite regular. The heart sounds were almost inaudible. The temperature, which was subnormal when the pain started, soon became elevated. The patient was very bad for three days, in spite of cardiac stimulants, and he became unconscious for about three hours on October 8th. After this date there was gradual improvement, and by the 12th the pain had gone, but the temperature continued to swing to over 101° F.

On October 14th, however, at 4 p.m., the pain returned in its original agonizing form, the position of maximal intensity being now in the epigastrium. It radiated to the back and down the inner side of the left arm. Severe collapse again accompanied the pain, and the patient was in a critical condition until October 23rd. By this time there was a slight icteric tinge in the conjunctivae, and the blood serum gave an indirect positive van den Bergh reaction. The liver was four fingers below the costal margin, and somewhat tender. The circulating leucocytes were found to number 18,000 per cubic millimetre, the differential count being: polymorphs 84 per cent., lymphocytes 13 per cent., monocytes 3 per cent. The blood pressure ranged about 90/70. On October 17th a pericardial rub was detected inside the apex, and remained audible until November 2nd.

Towards the end of October the cardiac dullness began to increase rapidly, and by November 5th there were signs of extensive pericardial effusion. On November 15th 6 ounces of fairly clear straw-coloured fluid were removed and examined. Red blood cells were present in fair numbers, and the lymphocyte was the predominating white cell. Guinea-pig inoculation was negative. The patient remained in hospital till November 16th, when he left at his own request. His condition was then fair. He had been almost free from pain during the last fortnight, and the temperature had begun to come down.

Apart from the fact that there were two distinct and typical attacks of severe pain, with collapse, there are some features of the case that deserve special mention. The age was much less than that at which infarction of the heart is usually seen. The great majority of cases occur between the ages of 50 and 70, although attacks are fairly common after 40. In a series of 145 cases analysed by Levine and Brown[1] only three were under 40, and Parkinson and Bedford[2] report 7 under 40 in a total of 183. These include two patients under 30, in both of whom coronary embolism was the cause of the infarction.

An acute pericarditis, as evidenced by a friction rub in the vicinity of the nipple and near the sternum, is not an uncommon feature of myocardial infarction. The development of pericardial effusion, however, seems to be rare. Levine and Brown found it in only one patient in their series. This was a man, aged 78, who had had cough and increasing dyspnoea for years. Parkinson and Bedford found it once among 100 cases seen clinically. X-ray evidence of effusion was present in their case ten days after infarction. In our case a friction rub was first heard three days after the onset of the second attack of pain, and enlargement of the cardiac area was detected about two weeks later.

We have not found any previous mention of pulmonary tuberculosis being associated with infarction of the heart. The latter occurs most frequently in patients with evidence of atheroma, hyperpiesis, or arterio-sclerosis, and in many cases there is a history of angina pectoris. Syphilis and rheumatic fever and gout are occasional causative factors. Levine and Brown point out that it is frequently associated with diabetes. In the case here

reported there were no clinical manifestations of any of these conditions. In spite of the fact that guinea-pig inoculation was negative, it is probable that the fluid was of tuberculous origin. Its characters and cytology suggested this, as did the prolonged irregular fever that accompanied its presence, although the latter may have been due to some extent to a reawakening of the pulmonary disease.

Electrocardiograms taken at frequent intervals after the first attack showed a normal P-wave and QRS complex in all leads. The so-called " coronary T-wave " was not present, but the portions of the curves normally occupied by the iso-electric R–T segment and the T-wave were made up of small undulations, each occupying about 0.1 second or less. This feature was most marked in Lead III.

Our thanks are due to Dr. D. L. Shrivastava, who took the electrocardiograms, and to Drs. K. K. Jaswal and Shujat Ali, house-physicians, for detailed notes of the case.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

NON-FILARIAL ELEPHANTIASIS

I was interested to read the account by Mr. D. J. Harries in the *British Medical Journal* (December 27th, 1930, p. 1079) of a case of non-filarial elephantiasis treated by a modified Kondoléon operation. Since these cases are rare I venture to record a case of my own treated in the same manner.

A female, aged 9, was admitted to the Hackney Hospital under my care in May, 1929, complaining of swelling of the left foot. The dorsum of the foot pitted on pressure, and in a few weeks the oedema had gradually spread upwards until the whole of the left limb was involved. The swelling was definitely painless; the skin was unaltered in colour, and apart from the inconvenience of fitting on a shoe the child had no difficulty in walking. A curious feature was that the oedema terminated abruptly at the level of Poupart's ligament in front and the posterior superior spine behind. The Wassermann reaction was negative, and the general health of the child was good.

For several weeks the patient was kept in bed, with the foot supported on pillows. Despite treatment by massage, electricity, and drugs, the limb continued to increase in size, but never did the oedema spread above Poupart's ligament. In March, 1930, it seemed justifiable to perform a modified Kondoléon operation. An incision was made on the outer side of the leg from the anterior superior spine to the external malleolus, and a strip of skin, 1½ inches wide, was removed together with a wider strip of oedematous subcutaneous tissue and deep fascia, the wound being closed with interrupted sutures. A similar operation was performed on the inner side of the leg, the incision extending from the saphenous opening to the internal malleolus. At intervals the muscle sheaths of the extensors were incised longitudinally. The subcutaneous tissue was markedly oedematous, and the deep fascia was not easily defined.

There was no alteration in the size of the limb for a week. A decrease was then evident in the region of the knee, and the whole of the area was definitely softer. For several weeks the child was kept in bed, and later the leg was rested on a chair, massage and electricity being administered regularly. Very little improvement, however, can be recorded as regards the dimensions of the limb, and the measurements taken in January of this year do not differ materially from those taken immediately before the operation. The general condition of the child at present is excellent. She walks without a limp, and the leg is growing normally. She is still, however, faced with the distressing prospect of an oedematous limb with almost the whole of her life in front of her.

It is interesting to compare this result with the more successful one obtained by Mr. Harries. He claims quite rightly that his result shows the value of a Kondoléon operation in the treatment of non-filarial elephantiasis. In the case I have described the effect was less striking. In fact, these divergent experiences bear out the accepted opinion that the results of the Kondoléon operation are not invariably completely satisfactory. Some writers have recorded cases which have responded to the operation with remarkable suddenness. In *Surgical Pathology* Boyd describes a case of a girl, aged 17, whose arm returned to its normal size four weeks after the operation. Six months later the left leg and foot became swollen, yet within four days of the operations on these limbs the swelling had subsided. Many other writers, however, have met with little or no success. One is forced to the conclusion that the operation is not to be entered upon optimistically, but since occasionally successful results have been obtained, such as in the case of Mr. Harries, there is no doubt that this treatment is worth a trial as a last resource. I agree with him that the operation is easy to perform, and there is little shock. Both cases support the statement that this disease is more common in females.

Assistant Surgeon, Great Western Railway Hospital, Swindon.

MECKEL'S DIVERTICULUM CAUSING ACUTE INTESTINAL OBSTRUCTION

In view of the following unusual termination of an attack of diarrhoea and vomiting in a boy aged 10 years, I think the facts may be of some interest.

The boy was first seen on account of diarrhoea and vomiting, which had followed a surfeit of fruit tart. The temperature was normal, pulse rate 80, and any gross abdominal lesion was excluded by examination. As a result of a diet restricted to albumin water and the administration of bismuth carbonate and tincture of belladonna, the vomiting ceased on the next day and the diarrhoea on the third day. On the fourth day the patient began to vomit again, and despite treatment vomiting became more frequent. The pulse rate remained about 80, there was no rise of temperature, and nothing abnormal could be found on abdominal examination.

On the fifth day the vomiting still persisted, and the patient complained of pain in the abdomen. He described the pain as " coming and going." The pulse rate was 100, and the temperature was normal. The boy had an anxious expression. Beyond a suggestion of tumidity, nothing could be made out on abdominal examination. The administration of two enemata at intervals of ten minutes resulted in failure to pass faeces or flatus, and he was removed to the Merthyr General Hospital as a case of acute intestinal obstruction.

The abdomen was opened by a right paramedian incision below the umbilicus, and an intussusception of the ileo-colic variety found. There was only slight difficulty in reducing this; the apex of the intussusception proved to be a Meckel's diverticulum about one inch in length with a flattened tip, the tip having an umbilicated appearance. This was removed, the gut sutured, and the abdomen closed.

The patient made an uninterrupted recovery.

Plasnewydd, Bedlinog, Glam. W. D. JENKINS.

VOLVULUS OF A LARGE APPENDIX EPIPLOICA

The following case, which presented rather misleading symptoms and signs, seems sufficiently obscure to be worthy of record.

A housewife, aged 50, was admitted to hospital on December 16th, 1930, complaining of abdominal pain and " anaemia." She had had a similar attack of pain five years before. On inquiry it appeared that for the previous three weeks she had suffered from acute intermittent epigastric pain, increasing in severity and worse after meals. She had vomited several times immediately after a meal; no haematemesis. Bowels usually regular, but diarrhoea present; no melaena; no blood per rectum.

On admission the patient was anaemic, the skin having a lemon-yellow colour. The tongue was dry and glazed. The abdomen was slightly distended, especially on the left side, and tender in the right epigastrium, where an indefinite mass could be felt. Per rectum a small polyp could be felt on the posterior wall; no faeces. Per vaginam nothing abnormal was discovered. A barium meal showed slight spasm of the pylorus and dilatation of the coils of small intestine.

On December 30th, under general anaesthesia, laparotomy was performed through a right paramedian incision. The stomach, pylorus, duodenum, gall-bladder, liver, appendix, uterus, tubes, and ovaries were each explored and found to be normal. There was slight collapse of the transverse colon, but otherwise the intestine showed no disease. On the sigmoid colon an appendix epiploica the size of a large broad bean was found. It was twisted about a very narrow stalk, and was of a dusky purple colour. There was no inflammation of the surrounding peritoneum. The mass was ligatured and removed and the abdominal wall closed in layers.

The tumour was ovoid in shape, its axes measuring 26 by 20 by 6 mm. Dilated veins covered its surface. Microscopical section showed fatty and connective tissue, the vessels in which were all congested, one containing definite clot. There was no inflammatory reaction.

The patient was discharged nineteen days after operation, her pain being cured. Convalescence was complicated by facial erysipelas.

House-Surgeon, Kent and Canterbury Hospital, Canterbury.

Reports of Societies

ERUPTIONS OF THE EXTERNAL AUDITORY MEATUS

At a meeting of the Section of Otology of the Royal Society of Medicine on May 1st, with Mr. A. R. TWEEDIE in the chair, Dr. H. W. BARBER opened a discussion on non-malignant diseases of the external ear, with a paper on eruptions involving the external auditory meatus.

Dr. Barber said that he would confine his remarks to conditions of primary importance or of special interest; he classified these eruptions into five groups—namely, those due to external infections, those due to infective organisms reaching the skin through the blood stream, those allergic in nature, those due to involvement of cutaneous nerves or nerve ganglia, and those which could not be included in any of the foregoing groups. Before discussing the classification in detail he wished to refer to the question of eczema. To diagnose eczema without adding a rider as to its cause was to make no diagnosis; like urticaria, eczema was a defensive reaction of the skin to injury. It began with oedema of the Malpighian layer, leading to separation of the prickle cells and spongiosis; this might go on to the formation of intradermal vesicles or bullae. Eczema was always an indication of epidermal sensitization, and was really an allergic reaction of the Malpighian cells. Erythema and urticaria affected the dermis, and erythema and eczema might occur at the same time, and as a result of the same toxin—for instance, in the case of rashes due to an injection of serum. Adrenaline controlled erythema, but had no effect on eczema. The first step in the diagnosis of eczema was to decide whether it was internal or external in origin; thus a person who was sensitive to iodine might develop eczema after taking iodine by mouth or after external application. The most important organisms in the group of eruptions due to external infections were pityrosporon, the pyogenic organisms, the tubercle bacillus, and fungi such as monilia, saccharomyces, and aspergillus. The skin might become sensitized to these organisms; by intradermal injection of an emulsion of the causative organism it was then possible to confirm the diagnosis. The injection gave rise to a local exacerbation, and on the third or fourth day the area became eczematous; a focal reaction also developed in the original site. Pityrosporon was one of the commonest causes of infective meatitis. Inoculation with cultures of the fungus produced seborrhoeic dermatitis; a pure fungus infection of the meatus by pityrosporon attacked the stratum corneum, giving rise at first to seborrhoeic dermatitis; this was soon followed by eczematization and secondary infection, either with *Staphylococcus aureus*, resulting in the development of boils, or with *Streptococcus longus*, resulting in the development of fissures. Thorough treatment of the infected scalp was indicated. A campaign against the uncleanliness of hairdressers might also be conducted. The acne bacillus attacked the infundibulum of the pilosebaceous follicle, giving rise to comedos, which represented the defensive reaction of the horny cells, and to an inflammatory reaction, with the development of pustules. The important infections due to staphylococci were boils and eczema, usually produced by *Staph. aureus*, or, more rarely, by *Staph. citreus*. Furunculosis was a frequent complication of a meatitis due to pityrosporon, and required treatment of the scalp and of the seborrhoeic state. The skin was constantly exposed to the dangers of infection with *Strep. longus*, either by contact with the infected skin of others, or from nasopharyngitis and gingivitis. Once acquired, the infection was extremely persistent; the organism invaded the folds of the skin, causing intertrigo and fissure formation; it might also give rise to impetigo contagiosa, eczematoid dermatitis, and even erysipelas. Fissure formation at the angle of the retroauricular fold was common with *Strep. longus* infections, and infection of the meatus was common in acute impetigo contagiosa.

All the organisms so far discussed might be harboured by the normal skin as saprophytes. It was desirable to discuss the factors predisposing to the adoption by them of a parasitic mode of life. With the staphylococci and pityrosporon, seborrhoea was the condition which most strongly predisposed to infection. The patulous sebaceous follicles swarmed with acne bacilli, and boils and sycosis were likely to develop. The growth of monilia was favoured by moisture; it was common in washerwomen and barmen, who had their hands constantly in water. The resistance of the epidermis was the first line of defence against these organisms. With streptococcal infections the antibody production of the skin and mucous membrane could be stimulated by the intradermal injection in graded doses of a vaccine made from the causative organism. There was reason to think that the same treatment might be effective with staphylococci and monilia. Infection of the ear with the tubercle bacillus was not very uncommon; lupus vulgaris usually began on the lobe and spread to the auricle, sometimes leading to occlusion of the meatus. Eruptions due to organisms reaching the skin through the blood stream were syphilides, such as condylomata and gummata, lupus vulgaris in certain cases, leprosy, and the exanthemata. Eruptions of internal origin and allergic in nature included erythema multiforme, erythema scarlatiniforme, lupus erythematosus, eczema, and probably psoriasis. Lupus erythematosus usually affected the helix and concha as well as the meatus; it gave rise to persistent erythema with telangiectases, and to scales due to hyperkeratosis; there was a tendency to superficial atrophy, and the scale, unlike that of psoriasis, was dry and adherent; its removal gave rise to pain and bleeding. The prognosis in this condition was better since the introduction of gold and bismuth therapy. In psoriasis of the meatus the skin of the scalp was nearly always involved. Eczema was commonly associated with other allergic conditions, such as asthma, urticaria, and migraine. The so-called "gouty" eczema, occurring in fat and plethoric patients, called for spa treatment. Eruptions due to

involvement of the cutaneous nerves or nerve ganglia included herpes *simplex*, prurigo, and herpes zoster. Herpes simplex was occasionally found on the auricle, and was presumably due to a filterable virus; herpes zoster might be part of a geniculate ganglion syndrome. Conditions which did not fall into any other group were: congenital malformations such as naevi, new growths such as epitheliomata, verruca vulgaris, and acanthosis nigricans, which was usually secondary to malignant disease in the abdomen.

Mr. T. B. LAYTON said that infections of the meatus due to suppurative otitis media were common, and were often due to the treatment applied to the middle ear. The seborrhoeic triad needed a moist skin for its growth. He had now abandoned the use of drops, and had his applications made up either with spirit or glycerin. The condition became chronic when secondary infection took place, and the first week of treatment was therefore most important. In older children and in adults the treatment was more effective when the patient did it himself, because its success depended on the time given to it.

Mr. E. WATSON-WILLIAMS agreed that treatment with watery applications should be avoided, but Mr. L. GRAHAM BROWN thought that syringing to remove debris was valuable before the introduction of applications with a spirit or glycerin base, or of yellow oxide of mercury ointment. Many cases of eczematoid dermatitis of the meatus were due, he considered, to irritation by the patient's finger; a man would notice a dullness in his ear, and attempt to clear it with his finger or a match. For this reason he always examined the nasopharynx of these patients to discover whether the cause of the dulled hearing lay there. Sir JAMES DUNDAS-GRANT asked whether Dr. Barber advised the routine bacteriological investigation of the discharge in eruptions of the ear.

In replying, Dr. BARBER said that he agreed that irritation of the meatus by the patient often caused a breech through which the *Strep. longus* might enter. In dealing with a pure infection the majority of ointments would do good, but if the skin became sensitized they were apt to cause aggravation. In such cases he used only weak ichthyol or tar ointments, but not resorcin, mercurials, or sulphur. It should be possible to say clinically what organism was responsible for a given eruption; in doubtful cases a bacteriological examination should be made.

CARE OF THE CHILD

At a meeting of the Liverpool Medical Institution, held on April 16th, with the president, Professor W. BLAIR BELL in the chair, Dr. LEONARD FINDLAY opened a discussion on the care of the child from birth to school age.

He said that the most appropriate introduction to the discussion was a consideration of the question of infant mortality, which still remained a most serious problem. Comparing the infantile death rates in England and Wales, and Scotland, he pointed out that until 1913 the death rate was higher in England than in Scotland, but since then the reverse had been the case. One of the chief reasons for this was the relative disappearance of epidemic enteritis, always more severe in England owing to climatic conditions. However, the simultaneous fall in deaths from this cause in various towns in Britain, Europe, and America suggested that the disappearance was in response to natural laws rather than the result of any human effort. Measles and whooping-cough were also responsible for a goodly proportion of infantile deaths, and one method of combating these diseases would be the provision of housing accommodation in order to lessen the opportunity for the spread of infection. He agreed that the relatively more rapid fall in the infantile death rate in England might be partly due to the intensive child welfare movement in that country. In England, since 1911, the deaths from convulsions and debility had fallen to a much greater extent than in Scotland. He emphasized, however, that there must not be too much supervision, or ill-directed interference with nature (as suggested by the rise in deaths from injury at birth). During the period of life under consideration environment exerted its greatest effect. Comparisons made between the urban and the rural child of the same social class showed a delay in growth of the former between the age of six and eighteen months. Tuberculous infection, and deaths from tuberculosis, were more numerous during the first year of life than during any single year thereafter. It was difficult to estimate the amount of tuberculosis contracted during early life, as much of it did not declare itself until later; but it was known that a great deal was due to the bovine tubercle bacillus transmitted by milk, and consequently preventable. Dr. Findlay urged that no efforts be spared to secure a pure milk supply and so eradicate this variety of tuberculosis. Tubercle-free milk must be supplied to rural districts as well as to the large cities, for there was good reason to believe that bovine tuberculosis was relatively more prevalent in rural districts and small towns.

Dr. NORMAN CAPON dealt mainly with the neo-natal period, and gave figures to show that, in spite of the gratifying reduction in the infantile death rate during the present century, there had been only a slight fall of mortality rate during the first four weeks of life. Every newborn baby still passed through a period of great danger to life, and, when he survived, he might have suffered damage which would jeopardize his future. It was an appalling fact that in 1929 47,868 infants died in England and Wales during the first year of life, and that 21,136 of these babies did not survive the neo-natal period. During the same year the total maternal deaths numbered 2,787. Dr. Capon emphasized the need for the closest co-operation between obstetricians and paediatricians. The former were in a position to employ prophylaxis when it might reasonably be expected to be most fruitful; it could be divided—to quote Eardley Holland's happy phrase—into the strategy of obstetrics (ante-natal supervision) and the tactics of obstetrics (conduct of labour).

Dr. H. R. HURTER spoke of the very high mortality at the close of the seventeenth century, even among children of royal birth. James II had succeeded in rearing only three of his twelve children, and his daughter Queen Anne had, when 37 years old, lost every one of her numerous progeny. The healthy child of 4 or 5 needed better exercise than the long monotonous walks alongside the perambulator of his younger brother; outdoor games and the garden sand-heap were better.

Dr. A. DINGWALL FORDYCE said that educationists and psychologists had extended knowledge on the mental side, and at the same time recognized the importance of physical factors and pathological states. The object in early years must be to preserve normality, and rational care should be under medical supervision. A unified medical service was necessary, and in order that such service be capable and reliable, undergraduate instruction in paediatrics must be developed.

The PRESIDENT said that he had long been of the opinion that obstetricians should surrender to the paediatrician the care of the child from the hour of birth. In the days gone by the obstetrician took charge of the baby; to-day it was rightly considered that the surgeon's responsibility in regard to this matter ended with the safe delivery of the child. During the last twenty years he had himself seen a great change in obstetrical interest in the life and freedom from injury of the child. Formerly the baby received scant consideration. Now, while the

interests of the mother still had, and always would have, a prior claim, the life of the child was an important factor in deciding the best method of delivery. He was therefore somewhat surprised to hear Dr. Findlay state that the percentage of birth injuries had been doubled. He thought that this statement was not strictly true, and was probably due to the fact that the frequency of fatal intracranial haemorrhages was not realized until a few years ago. There was another point in regard to child welfare which must not be overlooked by paediatricians—namely, that they were responsible for the production of the healthy mothers of the next generation. Many women came already crippled to ante-natal clinics to-day, and the reduction of the maternal mortality depended largely on the prevention of contracted pelves, not only those due to rickets, but also those, such as round pelves and justo-minor pelves, which were due to post-natal developmental errors. So, too, the disappearance of infections, including rheumatism in juvenile life, would diminish the number of cardiac, renal, and arthritic maternal cripples. He felt that the growth of paediatric science should confer obstetrical blessings on women.

LOWER SEGMENT CAESAREAN SECTION

At a meeting of the North of England Obstetrical and Gynaecological Society, held in Liverpool, Mr. ST. GEORGE WILSON read a paper on lower uterine segment Caesarean section, and showed a cinematograph film of the operation as performed by himself. After a concise historical survey Mr. Wilson reported the result in fifty of the fifty-four cases of which full details were available, and in which he had used this incision. Twenty-three were primiparae, twenty-seven multiparae, and fifteen had had previous Caesarean sections. In twenty-two of his cases there was general contraction of the pelvis, and in fourteen flat pelvis. There was one case of oblique contraction, and one of disproportion, which Mr. Wilson agreed with Mr. Leyland Robinson in ascribing mainly to deflection of the head due to or associated with imperfect functioning of the uterus. Pelvic tumours were present in four cases. In two, operation was done on account of cardiac disease. The remaining five comprised three patients with bad obstetrical histories, one with prolapse of the cord, and one elderly primipara with a breech presentation and rupture of the membranes of four days' duration. He thought that this incision extended the indications for operation, and that it also tended to diminish the number of operations performed. He considered that the textbook measurements of the pelvis were well above normal, and that a large number of cases labelled "generally contracted" would deliver themselves if given the chance of a trial labour. His operation rate at Walton Hospital was 1 in 14.3 deliveries. The average duration of labour in his fifty cases was 15.3 hours. The period of labour allowed was regulated by the condition of the foetus alone: the longer the labour the simpler the operation.

Various authorities were then cited by Mr. Wilson to show the greater morbidity rate in classical than in lower segment Caesarean section. He agreed with Munro Kerr that the uterine wound was infected from the interior by an ascent of bacteria from the vagina. In his series, excluding six cases of pulmonary disease and one of pyelitis, five were notifiable—a morbidity rate of 10 per cent. The average stay in hospital was 19.4 days. In addition to its immediate importance, he considered sepsis had a bearing on future pregnancies and labours. He thought, however, that the situation of the placenta over the previous scar was the important etiological factor in five of the six cases of rupture he had reported to the society. It was stated that the placenta was attached to the anterior wall in 40 per cent. of pregnancies. As well as the absence of placental attachment, the lower segment had the advantage that it bore no stress during pregnancy, or early in labour when rupture was most likely to occur in the classical scar. In regard to the children, there was one stillbirth—a hydrocephalic with spina bifida—and two neo-natal deaths (one soon after delivery, the other at ten days from gastro-enteritis).

A film of the operation was then shown and described. A catheter was kept in the bladder till the patient was put on the table. The position used was a moderate Trendelenburg. The abdomen was opened by a midline subumbilical incision, and a large Doyen retractor introduced. After careful packing off, a curved transverse incision was made as low down as possible in the utero-vesical pouch. The bladder was not pushed down, and a similar curved transverse incision was then made through the lower segment, the lateral extensions of the incisions being made with scissors. Pressure on the fundus forced the head down, and delivery was assisted by means of one blade of Simpson's forceps used as a vectis. Traction on the head then completed delivery. The placenta, as a rule, separated at once, and was delivered by traction on the cord. At this stage an injection of ergotamine phosphate and histamine was given intramuscularly. The incision was then closed by continuous catgut sutures in two layers, the decidua being avoided and the cut edges inverted. A third continuous suture closed the peritoneum. Graf's No. 3 catgut was used throughout. Mr. Wilson had never left the placenta to be delivered *per vias naturales*. He referred, in closing, to the easy convalescence of these cases, to the absence of intestinal complications, and to the advantage of confining any infection to the pelvis and behind a loosely attached peritoneum rather than allowing it to spread through the adherent upper segment peritoneum to the higher parts of the abdominal cavity.

Professor W. BLAIR BELL showed a uterus with attached portion of colon removed at operation for a utero-colic fistula due to carcinoma. He also described a case of intrauterine pregnancy occurring subsequently to conservative operations for different lesions, first on one tube and later on the other. Professor Blair Bell and Mr. LEYLAND ROBINSON each described cases of fibromyomatous uteri simulating pregnancy. A specimen of torsion of a hydrosalpinx was demonstrated by Mr. N. L. EDWARDS; and Mr. ST. GEORGE WILSON showed a uterus which had spontaneously ruptured during unassisted delivery of the child.

INTRACRANIAL TUMOURS

At a meeting of the London Jewish Hospital Medical Society on April 16th, with the president, Dr. LEOPOLD MANDEL in the chair, Dr. GORDON M. HOLMES read a short paper on modern advances in the diagnosis of intracranial tumours.

Dr. Gordon Holmes said that as tumours might occupy any region of the brain, all possible signs of neurological disorder might be produced. Localizing the position of a tumour was always interesting work, as it was a sporting task, which could be checked by the surgeon. Treatment had not advanced in the same way as diagnosis and localization, as 60 to 70 per cent. were gliomata, which were spreading tumours and therefore difficult to extirpate surgically; here lay a possible advance in treatment by *x* rays or radium. The diagnosis of tumour was made by the presence of increased intracranial pressure, evidence of local disease, and symptoms of irritation. Increase of intracranial pressure was brought about either by the size of the tumour itself in the closed cranial cavity, by reactionary changes around the tumour

(especially malignant metastases), or by interference with the circulation either of blood or of cerebro-spinal fluid. Headache, vomiting, and optic neuritis were the classical signs, but any two of these were sufficient to make one strongly suspect its presence. The diagnosis became certain, when, in addition to increase of pressure, there was disturbance of function (depending on the site of the tumour) pointing to local disease; this was generally of gradual development. Irritative phenomena might take the form of local epileptiform seizures, of which tumour was the commonest cause. These sudden disturbances might be brought about either by reaction around the tumour, haemorrhage into the tumour, extension involving new structures, or by obstruction of the flow of cerebro-spinal fluid. The signs of cerebral tumour must be differentiated from those of: (1) primary degenerative changes, in which there was no rise of pressure and the lesion was diffuse and bilateral; (2) chronic uraemia, which could be diagnosed from an examination of the urine, blood vessels, and blood pressure; and (3) cerebral arterio-sclerosis. The mathematical accuracy of localization was interfered with by disturbances of other parts of the brain by such factors as displacement and the increase of pressure; but, in spite of this, by clinical methods alone, 80 to 90 per cent. could be localized. Dr. Gordon Holmes wished particularly to draw attention to disturbances of sensation and of vision which occurred with tumours of the forebrain. There was no marked disturbance of cutaneous sensation, but discrimination was affected in the sense of position of the limbs, stereognosis, and the recognition of simultaneous contact of two points in the compass test. There might be gross disturbance of the visual fields, such as homonymous hemianopia. Visual inattention on the simultaneous exhibition of two objects occurred with superficial lesions of the parietal and occipital lobes; and visual disorientation was especially found with lesions of the left side of the brain. Recent advances in aids to localization had proved of little true value. *X* rays were occasionally useful, but the interpretation of the skiagram was difficult. Pneumoencephalography was attended by an 8 per cent. mortality; and the more careful the clinician the less use there was for this method. Injection of the carotid artery with sodium iodide solution was dangerous. Auscultation of the skull might reveal a vascular tumour or aneurysm; and percussion of the skull might reveal a tender area over the tumour. The important point to be remembered was that time and repeated examinations might be necessary before the tumour could be definitely localized.

Mr. JULIAN TAYLOR then read a short paper on results in surgery of intracranial tumours at the present time. He said that he did not intend to enter into details of technique, but would limit his remarks to the question of prognosis. Compared with many other branches of surgery, the results of intracranial operations presented a high mortality. In contrast there was a small proportion where complete success was attained and a larger where disease was arrested and patients had returned to nearly normal health. The variability of the results and the undoubtedly high proportion of failures were to be accounted for by the large number of conditions for which cranial operations were undertaken, and by the complexity of their effects on the brain. Percentages were useless in estimating the prospects of a particular case, and to make a prognosis the following factors had to be considered. (1) The nature of the tumour. The majority of intracranial tumours were malignant infiltrating neoplasms that were not associated with secondary growths. Some 60 per cent. were gliomas which infiltrated the brain but not its coverings. Their malignancy varied and their growth might sometimes be completely arrested. Only a very small proportion could be treated by irradiation. Some 12 per cent. were endotheliomas (meningiomas), which displaced the brain but infiltrated its coverings. Their malignancy was practically constant, and their infiltration was so slight that in practice it might almost be neglected. The remainder were for the most part benign, pituitary, acoustic, congenital, and angiomatous tumours. (2) Accurate localization of the tumour. In spite of the accuracy of modern neurologists, certain knowledge of position or size was not always available. (3) The accessibility of the tumour. Examples of partly accessible tumours were subcortical tumours growing deeply towards the corpus callosum or basal ganglia. (4) Permanent loss of cerebral function. In the majority of intracranial tumours that were operated on, the neurological signs and symptoms were due more to temporary vascular effects of the growing tumour than to actual destruction; so that removal of a tumour or decompression might result in recovery from symptoms. The visual paths and cortex were exceptions, and rarely showed signs of recovery. (5) The degree of increased intracranial tension. In a large number of cases high intracranial tension made surgical relief of the greatest difficulty. Methods were available for mitigating this danger. When papilloedema resulted in atrophy, return of vision was not to be expected. (6) The situation of the tumour. There were difficulties special to most tumours—for example, tumours in the neighbourhood of the left Sylvian fissure or of the left motor cortex could rarely be removed on account of aphasia and right hemiplegia. Tumours in the posterior fossa were dangerous on account of haemorrhage from cerebellar vessels and of the proximity of the medulla, which prevented any but the slightest manipulation. (7) Palliative decompression. For decompression to produce relief, it must be over the tumour. Where there was hydrocephalus decompression might give little relief, especially in the posterior fossa. The site of obstruction to the cerebro-spinal fluid, whether on its outward or return flow, was an important factor in the posterior fossa. Decompression either above or below the tentorium was rarely productive of benefit in tumours obstructing the incisura tentorii. Mr. Taylor concluded by giving a short summary of results in cerebral tumours. In gliomata the results were variable. In endothelioma the progress depended on the size of the tumour and the duration of the increased intracranial pressure; recurrence in the coverings was unfortunately too frequent. Pituitary tumours in some cases could be operated on successfully, but deep *x*-ray therapy seemed to hold some hope. Diathermy in the removal of some growths had met with success.

Mr. H. S. SOUTTAR said that, like Mr. Julian Taylor, he was not one of the optimistic surgeons referred to by Dr. Gordon Holmes, but he did think there was still much scope for them in the field of cerebral surgery. He pointed out that the symptoms displayed by the patient were often quite out of proportion to what was found at operation. In one case, a very small tumour gave rise to an immense hydrocephalus; in another, a huge tumour of the parieto-frontal region was found at operation, and the only symptom displayed by the patient had been extreme cheerfulness. Mr. S. I. LEVY recorded a case of cerebral sarcoma, treated by radium after decompression. the patient had lost his symptoms and was now carrying on a normal life.

In reply, Dr. GORDON HOLMES thought there was a future for *x*-ray therapy in certain types of tumours. With regard to radium, the results at Queen Square had so far been disappointing. He stated that he had not laid much stress on the mental symptoms associated with cerebral tumours, as he found that when he entered into the field of psychology he never felt too happy.

Reviews

CANCER AND RACE

The experienced statistical reviewer opens a book bearing this or a similar title with misgiving, for cancer and race taken separately are potent stimulants of crotcheteers and in combination are formidable. Dr. MAURICE SORSBY's little book[1] is an agreeable surprise; it may be that in some passages he has allowed more weight to imperfect data than they can properly bear, but, on the whole, he has maintained a judicial attitude which is very refreshing, and the conclusions he reaches are of real interest and importance. Dr. Sorsby has made a point-to-point comparison of the incidence of cancer upon Jews and non-Jews wherever statistical data were obtainable, and these are the results he has reached. Cancer *as a whole* falls with equal incidence upon Jews and non-Jews. The wide geographical variations (in part, perhaps, due to real differences of incidence, in still greater part due to varying exactitude of recording) are as closely reflected by one section of the population as the other. When, however, one scrutinizes the site rates there is quite clear evidence that Jewish women suffer less from fatal cancer of the uterus than non-Jewish women, and fairly clear evidence that cancer of the intestinal tract is rather more prevalent among Jews than among non-Jews. Hence we must conclude that not race, but habits of life, are responsible. What may be the factor of intestinal cancer is a matter of vague speculation, but quite plausible reasons for the advantage enjoyed in respect of cancer of the uterus can be furnished. A good deal of evidence has been supplied by gynaecologists, especially Peller, that septic traumata at the cervix uteri may be of etiological importance. But the ritual observances of the Jews impose upon strict members of the faith a much higher standard of cleanliness of the female sexual organs than is observed by non-Jews of the same social class. Hence it is reasonable to believe that the lower rate of mortality from cancer of the uterus is to be explained in this way. Collateral support is afforded by the evidence that cancer of the penis is very much rarer in circumcised than in uncircumcised peoples. The case is also strengthened by evidence that with a tendency to depart from the ancient ways has gone some tendency to equalization of rates as between Jews and Gentiles. Dr. Sorsby's book is well worth reading, and fully deserves Dr. F. E. Fremantle's commendatory preface.

A TEXTBOOK OF PATHOLOGY

With the publication of Professor E. T. BELL's *Text-Book of Pathology*[2] another addition is made to the long list of books on that subject from which the student has to make his choice. He may well ask in what these numerous works differ, and in what respect one is to be preferred to another where all may claim to be of equal authority. There is no doubt that it is desirable, for its proper appreciation, to bear in mind the point of view from which a book is written, and with regard to works on pathology a certain evolution in this respect can be discerned. The earlier works were, in the main, textbooks of pathological anatomy; then gradually the notion of function was introduced, and finally the functional standpoint became predominant and anatomical considerations took a secondary place, as in Krehl's textbook. A later development consisted in completely discarding the anatomical standpoint and adopting that of causation as the basis of classification, of which MacCallum's *Pathology* is a good example. Works on clinical medicine and surgery have always included pathology in their scope, but as the latter subject has increased its bounds, it is found convenient to deal with it separately, and thus have arisen works on pathology written from the clinical standpoint. Professor Bell's textbook belongs to this class. He has aimed at bringing the descriptions of structural changes in disease into relation with the problems of clinical teaching, and the classification adopted corresponds to clinical entities as far as possible and to the etiology of disease, although in the present state of knowledge purely anatomical considerations are unavoidable in certain directions.

The general plan of the book can be inferred from the above. It is well written, and kept within moderate bounds without any loss of comprehensiveness. Professor Bell has taken several colleagues into collaboration, a course which some may consider a disadvantage as in some degree marring the unity of a work, but which the progress of knowledge seems to have rendered inevitable. The illustrations must be specially mentioned. Many are drawings which for truth and artistic merit deserve great praise. The majority are photographs, and these, again, are of quite exceptional excellence; they show the changes intended to be shown, and they prove that photography used in illustration of pathological lesions, although very often an entire failure, is capable of giving results which compare favourably with those obtained by any other process. In this and other respects Professor Bell's *Pathology* is an attractive book, and is certain to take a place among the best textbooks on the subject.

A matter of no small importance is briefly referred to by the author—namely, the burden of nomenclature; he suggests that this would be materially lessened if some standard could be agreed upon. Certain it is that medical science is suffering severely at the present time from what may not inaptly be called "hypernomenclaturosis."

TREATMENT OF SKIN DISEASES

The Treatment of Skin Diseases in Detail,[3] by Dr. NOXON TOOMEY, is a volume of a rather unusual type. Very few books are written on the treatment of skin diseases, and most of these are very sketchy. Dr. Toomey, on the other hand, has produced a treatise which really fulfils the promise of its title, and gives sufficient particulars and explanation to enable a practitioner to carry out the measures recommended. Every cutaneous condition is considered separately under its own name, and after a short disquisition on the nature of the problem in each instance full directions are given for its solution. As must inevitably happen, there is a good deal of repetition, and this makes the book rather tiresome for continuous study, but it is one which may with advantage be consulted at any time in the hope of finding something useful for a special case. It will not, of course, dispense with the necessity of laying the only true foundation to successful therapy, which is to make the correct diagnosis. Most of the avoidable failures in the treatment of skin disease are due to the fact that this has not been done.

This is the third volume of Dr. Toomey's treatise on the principles and practice of dermatology. No doubt the second one, on diagnosis (which we have not seen), will have adequately prepared the way for his readers to take full advantage of the work before us. Dr. Toomey is quite up to date in his methods in general, but we should have expected to find more about the treatment of varicose ulcers and the influence on them of injection of the

[1] *Cancer and Race*. By Maurice Sorsby, M.D., F.R.C.S.Ed. With a preface by Lieut.-Colonel F. E. Fremantle, M.D., M.Ch., D.P.H., M.P. London: J. Bale, Sons and Danielsson, Ltd. 1931. (Pp. 120. 7s. 6d. net.)

[2] *A Text-Book of Pathology*. Edited by E. T. Bell, M.D., F.R.C.P., F.R.C.S. London: H. Kimpton. 1930. (Pp. xxxviii + 627; 316 figures, 2 plates. 36s. net.)

[3] *The Treatment of Skin Diseases in Detail*. By Noxon Toomey, M.D., F.A.C.P. Principles and Practice of Dermatology, vol. iii. St. Louis, U.S.A.: The Lister Medical Press. 1930. (Pp. 512.)

varicose veins. In psoriasis he is of opinion that the most effective internal treatment is colloidal gold, which he ranks superior to arsenic, still considered among ourselves the most useful drug in this lesion. The chapter on the treatment of lupus vulgaris is full, and for the most part quite sound, but we do not think that he is sufficiently emphatic on the dangers of *x*-ray therapy in this disease. In lupus erythematosus he has great faith in the employment of gold-sodium-thiosulphate, better known in this country as sanocrysin. He also recommends colloidal gold by the mouth. This is a modification of the treatment as yet not much in vogue among ourselves. Like most other dermatologists, he has come to the conclusion that the local applications most useful in this disease are those which are of a mild and soothing character.

Dr. Toomey's publishers have produced the book well, on good paper, and excellently printed. There are no illustrations, but these are not really called for in a work dealing with treatment only; no doubt his volume on diagnosis is amply illustrated. We have no hesitation in saying that this book will be found useful by practitioners who already possess some knowledge of dermatology and desire to enlarge their therapeutic resources.

CHRONIC RHEUMATISM

It is well that public attention should be directed to the problems of chronic rheumatism, a field so wide as to justify considerable latitude of treatment. Dr. B. L. WYATT's popular account of *Chronic Arthritis and Rheumatoid Affections*[4] is designed to supply information which will be acceptable to the patient as well as to the practitioner. In a prefatory note Dr. van Breemen claims that the treatment of rheumatic diseases has become more hopeful since an endeavour has been made to study and treat them in their early stages. A useful chapter on the incidence of these diseases in the United States is contributed by Mr. L. I. DUBLIN of the Metropolitan Life Assurance Company of New York. He quotes returns showing that on the eastern sea-board rheumatism constitutes about 9 per cent. of all illnesses, with a prevalence twice as heavy as that of tuberculosis and second only to accidents. The negroes of West Virginia and North Carolina appear to be much more liable to rheumatic affections than the white races. Dr. Wyatt believes that the majority of such cases in the States receive treatment outside the medical profession, although they are generally suitable for out-patient clinics. He seems well aware of the dangers of vague diagnosis and obscure terminology, and yet he increases rather than dispels the fog by identifying the term "rheumatoid" with "fibrositis," and mixes pathological anatomy with etiology by indifferently calling the same form of arthritis "proliferative" or "infectious." More to the point are his references, from personal knowledge, to the influence of chill and of climate. He finds in Southern Arizona (where the climate is dry and very sunny) very little infective arthritis, though there is much dental trouble. It is suggestive that of the men drafted from Arizona to the war less than one in a thousand suffered from arthritis—the lowest incidence in the United States. Dr. Wyatt advocates the routine provision of a warm atmosphere at all places where patients are under treatment for rheumatic disease, whether hospitals, sanatoriums, spas, or hotels, as in this way favourable results are much enhanced. Heliotherapy, however, is his favourite prescription, under which he claims improvement in 94 per cent. of cases.

PHYSICAL AND ORGANIC CHEMISTRY

The sixth edition of *Recent Advances in Physical and Inorganic Chemistry*,[5] by Dr. A. W. STEWART, gives a full review of the developments of research in the sphere indicated by the title. Much of the subject-matter, as might be expected, is concerned with research in the various lines of approach to knowledge of the structure of the atom. Special chapters deal with radio-activity and the disintegration of the elementary atoms, followed by others which treat of the consequences of such disintegration—namely, the generation of different elements having the same atomic weight and of elements of the same identity having different atomic weights. Other chapters deal with the atomic nucleus and the outer sphere of the atom.

A claim for the existence of a new element is not in these days entitled to consideration unless the element has properties qualifying it for one of the vacant numbered places in the ordered arrangement of the elements. Special interest is therefore attached to a chapter entitled "The roll call of the elements." This gives an account of the more recent claims to discovery in regard to new elements, acceptable evidence in favour of the existence of sundry new elements, and a consideration of the characters of those whose places are numbered but not yet filled with certainty. Abnormal forms of hydrogen and some new hydrides present another subject of interest in which tin hydride and lead hydride are shown definitely to exist. The effects resulting from the properties of the Donnan equilibrium are explained and their important relation to biological phenomena is demonstrated. In this edition there is a notable quantity of new material, particularly chapters dealing with line spectra, emission bank spectra, and continuous emission spectra. The book contains a valuable summary of the new work and of its more important bearings on kindred science.

NOTES ON BOOKS

The fourth volume of the fortieth series in *International Clinics*[6] is divided into seven sections, devoted respectively to: translations of French clinical papers; post-graduate lectures; paediatric contributions from the Fifth Avenue Hospital of New York City; further clinical contributions from the same hospital; medicine; medical questionaries; and the Meeting of the British Medical Association held at Winnipeg last year. The papers calling for special notice are those on the treatment of boils and carbuncles, by de Keyser of Paris; treatment of cardiac diseases, by James E. Tolley, professor of cardiology in the University of Pennsylvania; the care of patients in the terminal stages of cancer, by Norman Treves of New York City; toxin-antitoxin immunization in adults, by Joseph Lintz of New York City; post-partum fever, by John E. Tritsch and Frances E. Shields; hereditary epistaxis, by Hyman I. Goldstein; and the differential diagnosis of peptic ulcer, by I. W. Held and A. Allen Goldbloom.

Colonel R. J. BLACKHAM had a distinguished career in the Army Medical Services, and was a recognized authority on the Ambulance Department of the Order of St. John. His book, entitled *Scalpel, Sword and Stretcher*,[7] is an autobiography. Colonel Blackham began his professional life as a doctor's apprentice in Ireland. He worked hard under financial difficulties, but matricu-

[6] *International Clinics.* Edited by Henry W. Cattell, M.D. Philadelphia. Vol. iv, fortieth series. London: J. B. Lippincott Company. 1930. (Pp. viii + 309; illustrated. 12s. 6d. net.)

[7] *Scalpel, Sword and Stretcher.* By Colonel Robert J. Blackham, C.B., C.M.G., C.I.E., D.S.O., M.D. London: Simpson Low, Marston and Co., Ltd. 1931. (Pp. xi + 340; illustrated. 12s. 6d. net.)

lated and qualified in medicine, and then turned to seek fame and fortune beyond his native country. Before joining the Army he sailed to India and to Montreal as ship's doctor, and also experienced the joys and troubles of general practice. Then follow chapters dealing with life at Netley in the time of Sir Almroth Wright; the author's early military training at Aldershot; a tour of duty in India; a period of home service; a second tour of duty in India; the great war and after. He saw hard fighting at the battle of the Somme and at the third battle of Ypres. He served in Italy, and, returning to France in May, 1918, took part in the final advance to victory. He was sent to North Russia, but was invalided home before taking any active part in the fighting there. On his return he was appointed an administrative medical officer until his retirement on pension. Close contact with a fighting formation, followed by retirement and leisure to dwell on the past, sometimes gives one an exaggerated idea of one's own work, which history does not always support. In Colonel Blackham's autobiography several administrative measures which he instituted on his arrival in France were already in common practice in other divisions and corps. Interesting anecdotes of races, countries, and famous people he has come across in the course of his duty are interspersed throughout, and, like the majority of Irishmen, he delights to bring stories into his narrative. Some are racy, others amusing, but a few at this late date have been worn thin by repetition. On the whole, his experiences at home and abroad were common to all serving officers, and for that reason the book is rather colourless. It is written in a stilted style of short paragraphs and great detail, which may be necessary in staff work, but detract from the interest of the general reader. Outstanding, however, is the historical narrative of Colonel Blackham's work in organizing the Order of St. John in India, when he toured six thousand miles over British India and Ceylon with the minimum of expense and the maximum of hospitality from Mussulman, Rajput, Mahratta, Sikh, and Hindu princes. He was largely responsible for making the Order efficient and fit to play a worthy part in the Empire's titanic struggle during the great war.

The Proceedings of the third meeting of the German Society for the Study of the Circulation[2] comprise an account of discussions, which reached a far higher standard than those of the earlier meetings, and English workers will find much of interest in them. The reader is at first impressed by the continuity of the various papers, but a little reflection shows that there is but one main subject, the transport of oxygen, underlying all the problems of the circulation, so that a thorough treatment of any aspect of it must necessarily lay bare the underlying framework. The difficulties in measuring the cardiac output are clearly described in various papers. Bürker has contributed a very interesting account of certain constants of the red blood cell. There is a breadth of view in these discussions that augurs well for an early resumption by German pathologists of their prominent pre-war position.

The Proceedings of the Nineteenth International Congress against Alcoholism,[3] held at Antwerp in August, 1928 (see *Journal*, 1928, ii, 513), have recently been published and distributed to the members of the congress. The volume includes papers on alcohol and social hygiene, the medico-legal diagnosis of drunkenness, the economic aspects of alcohol, the question of personal liberty in the campaign against alcoholism, control of the sale of spirits in Sweden, alcohol and heredity, the economical results of prohibition in America, the campaign against alcoholism in Austria, legislation to protect children from alcohol, the Belgian law of 1919 on alcohol, alcohol and sport, welfare centres for alcoholic subjects, and the production and sale of non-alcoholic fruit juices.

ROGER CASEMENT

A PROBLEM IN PSYCHOLOGY

It is well-nigh impossible to read the moving story of *The Life and Death of Roger Casement*,[1] so excellently told by Mr. Denis Gwynn, without feeling that this man was not of the stuff of which traitors are made. Courage, high endeavour, vision, and the will to override all obstacles at whatever personal risk—by common consent he possessed all these in notable degree, blended with the gift of friendship, a profound compassion for the oppressed, and a faithfulness, even unto death, to a cause which he believed to be a just one. And yet, thus splendidly endowed for the heroic tasks he accomplished in the tropical forests and swamps of Africa and Brazil in the cause of suffering humanity, and after a score of years spent as a trusted servant of the Crown, he was found guilty on incontestable evidence of attempting to seduce the allegiance of British soldiers, prisoners of war in Germany, and of assisting the King's enemies while Britain was fighting for her existence.

An antinomy so amazing, a discrepancy between character and conduct so striking, could not but raise doubts as to his sanity, and as to whether the same flaming zeal which had burnt the bonds and swept away the tortures, and torturers, of thousands of natives in Belgian Congoland and the Putumayo, had not at the end consumed, or at least warped, his own reason. Certainly he had suffered enough, in both body and mind, to warrant such an assumption. When he returned from the Putumayo for the first time, his powerful frame wasted and his health undermined, Mr. Gwynn says he was a tragic figure to his friends, and it was painfully evident that, though still under 50, he had not long to live. Yet a year later, impatient of official delays in ending once and for all an iniquitous system by which in twelve years 4,000 tons of rubber had been carried to the London market at a cost in human life of 30,000 Indians, by starvation, or by deliberate murder, by bullet, fire, beheading, or flogging to death, accompanied by atrocious tortures, he was once more back at Iquitos. The storm of indignation which burst in England and America on the publication of Casement's report and the entire official correspondence after his renewed effort; the compulsory winding-up of the Brazilian Company, and the establishment of a new regime, will still be remembered; but Casement's health was now completely broken down, his official career at an end, and "an invalid, disillusioned and haunted by vile memories that could never be effaced," he retired, a ghost of his former self, to seek refuge in the quiet valleys of his own people in Ireland. And so returning—this was the spring of 1912—hoping for peace of mind at last, he found his country divided into two hostile camps, in a fever of political excitement, and, like The O'Neill who went home to Tyrone from the court of Elizabeth, even if he did not seek it, "rebellion lay in his way, and he found it." From this point onwards Mr. Gwynn describes, in language worthy of his subject, though more with the skill of a brilliant advocate than that of an impartial historian, the march of contemporary events which hurried Sir Roger Casement, a willing victim, to his doom.

So tragic an ending to such a career would invest almost any life with psychological interest, but Roger Casement's, as revealed in Mr. Gwynn's narrative, discloses features —some obvious and mentioned in detail, and others less striking—of perhaps considerable significance in this respect. A marked change in behaviour and habits and

[1] *The Life and Death of Roger Casement.* By Denis Gwynn. London: J. Cape. 1930. (Pp. 444; 8 illustrations. 12s. 6d. net.)

of sentiments and loyalties is so characteristic of many forms of mental disorder that the very influential signatories, including Sir Clifford Allbutt and Sir Thomas Barlow, who appealed to the Prime Minister that the extreme sentence of the law should not be inflicted, called attention in the forefront of their petition to "the violent change which appears to have taken place in Casement's previous sentiments to Great Britain," as well as to "the severe strains to which he had been exposed during his honourable service and to the tropical fevers he had endured." But there was no such violent change. Extracts from his own diary, referring to the years 1905 and 1906, when he was at home on leave, show conclusively that his hostility to British rule in Ireland was of long and slow development, even if it was not until February, 1914, that his hatred of English rule, as Mr. Gwynn says, became an obsession that henceforward dominated all his mind. At what stage of his career this dominance of the emotions over the reasoning faculties began can be merely conjectured. So far as it is revealed in these papers, the whole background of his life seems to have been a battle-ground of conflicting loyalties. No doubt for good and sufficient reason Mr. Gwynn barely touches on his childhood and adolescence, but at the end of his story he relates one fact of significance to the psychologist. In his last days, when awaiting execution, his hopes, ambitions, achievements, anxieties, and disillusions all behind him, Roger Casement, brought up as a Protestant, remembered that as a child he had been taken to a Roman Catholic chapel by his mother, who was a non-practising Catholic, and that there a priest "had splashed water on him." Seeking to resolve his last remaining doubts, and to be admitted to the Catholic faith—for he had long been a free-thinking rationalist—it was discovered that he was already a Catholic, though, Mr. Gwynn says, "he had never known it." In one way this may be true, but it is an elementary fact, almost a commonplace, that childish impressions, with a powerful emotional complement such as this, even though they may fall below the reach of voluntary recall, never die, but live and grow underground, beneath the threshold of consciousness, and some day send up shoots into the open. It may well be that this was the first of a long series of internal conflicts. Later, though determined to avoid the trammels of officialdom in the Civil Service, his desire for adventure and escape carried him by a side wind into the Consular Service. In Congoland his love of freedom and of open spaces, his hatred of oppression, and his sympathy with the oppressed, all chimed with the call of duty, and, difficult and arduous as his tasks were, these were probably his best and happiest years. Nevertheless it is difficult to avoid the conclusion that it was there also, daily witnessing and collecting the evidences of appalling atrocities, revolting merely to read about, inflicted on a harmless people, that he began to range himself definitely on the side of the governed and against the Government. It would seem, therefore, that when he returned to Ireland from the Congo, and certainly when he came back from the Putumayo, his mind was already prepared to espouse such a cause as Irish independence and revolt, and to see in Ireland the oppressed and in England the oppressor. In the conflict of loyalties which ensued the result could be foreseen.

There are no water-tight compartments in the mind. However convenient it may be to treat *separately* of affective and of intellectual states, they are so intimately tied, and so great is the dynamic influence of the affections upon the association of ideas, that disorder of one is seldom, if ever, to be found unaccompanied. Although Mr. Gwynn does not suggest that Sir Roger Casement was ever insane, and although the official statement issued on August 14th, 1916, the day after his execution, says that

> "another suggestion that Casement was out of his mind is equally without foundation. Materials bearing on his mental condition were placed at the disposal of his counsel, who did not raise the plea of insanity. Casement's demeanour since his arrest, and throughout and since his trial, gave no ground for any such defence, and, indeed, was sufficient to disprove it,"

evidences of a progressive intellectual perversion are not lacking. The narrative of his doings in Germany, for a man of his calibre, his absorption with petty affairs, his naïve trust in untrustworthy persons, and his groundless suspicions of others, makes pathetic reading, not to speak of his extraordinary belief that the Irish Brigade he tried to raise in Germany could attack England at war without serving any German end. In this connexion a letter from the Irish-American John Devoy is of interest. He describes Roger Casement in 1914 as a visionary, honest but utterly impracticable, "obsessed with the idea that he was a wonderful leader," that he alone, by his personal influence, could bring about the liberation of his country, "and seems, in fact, to credit himself with supernatural powers." Probably this description of Casement, written in some bitterness of spirit—for the writer blamed him for having wrecked the Irish rising—would not be accepted by his friends who had known and almost worshipped him in happier days; but it is at least curious that it adds to Mr. Gwynn's portrayal certain features which, if truly drawn, and if taken in conjunction with Casement's later activities, cannot but bring to mind the peculiar orientation, egocentric attitude, and tendency to persecutory ideas, combined with a remarkable retention of logical processes, which are in general characteristic of a form of mental malady fitly named "near to wisdom." Deeply rooted in the nucleus of the emotions, so gradual of development that those nearest mark no change from month to month and regard the early stages but as the unfolding of an unusual or visionary character, its victims are seldom recognizable as disordered of mind until the insistent promptings of unbalanced emotion have been rationalized into intense conviction and translated into action, and not always even then.

That Sir Roger Casement was "out of his mind" in the usual acceptation of the phrase cannot be maintained. He was well aware of the hazard he played and of the forfeit that would be claimed. He had even envisaged and feared the possibility of an attempt to find him "guilty but insane." On the other hand, a survey of the facts recorded here strongly suggests that there existed for long, though developed and fostered by years of intolerable strain, an abnormal emotive state—*interfering with and finally subjugating the normal synthesis of thought, transforming his whole outlook, long before he became involved in the political excitements of his country preceding the war—which subverted his judgement, deflected his high aims, overthrew his allegiance to the Crown, and brought a career of notable accomplishment to an inglorious end.*

C. B.

A special general meeting of the Fellows of the Royal Society of Medicine will be held at 1, Wimpole Street, W., on Tuesday, May 19th, at 4.30 p.m., to consider a request by the members of the Sections of Balneology and Climatology, and of Electro-Therapeutics, for the abolition of these Sections. The council proposes, in replacement of them, the creation of two new Sections: (1) of Physical Medicine, to provide for the study of balneology, climatology, and electrology; and (2) of Radiology, for the study of radiodiagnostics and radiotherapy. A majority of two-thirds of the Fellows voting will be required in order to make the proposal effective.

CANCER OF THE LIP, TONGUE, AND SKIN

MINISTRY OF HEALTH MEMORANDUM

The eighth memorandum of the Ministry of Health for the guidance of local authorities in the prevention and treatment of cancer has just been published.[1] In the *British Medical Journal* of August 16th, 1930 (p. 253), there was an article dealing fully with Dr. Janet Lane-Claypon's valuable report on cancer of the lip, tongue, and skin. The present memorandum also treats of cancer of the lip, tongue, and skin, including a statistical analysis of published writings on cancer of these parts of the body, which, with the breast and the uterus, have one important characteristic in common—namely, accessibility; important because early recognition by the public of cancer of accessible organs is the basis upon which the Ministry of Health wishes to found health instruction in this disease. Facility of access means, for the doctor as well as for the patient, easier and earlier diagnosis, not only of cancer itself, but also of the simple precancerous states which have been proved to be causally related to and to precede the development of malignant tumours and ulcers. The memorandum lays great emphasis on these precancerous conditions, which include cracks, fissures, chronic ulcers, warts, moles, pimples, scars, and leucoplakia—in other words, any source of chronic irritation—the avoidance and early detection of which will rest, in the main, with a properly educated public. Mortality rates show that cancer of these three organs is about three and a half times more common in men than in women, accounting, in men, for about 9 per cent. of the total deaths from cancer.

Cancer of the Lip

In 1928 in England and Wales 304 men and 25 women died from cancer of the lip, the mean age at death being about 70 years. The frequency with which cancer is preceded by some innocent condition has already been mentioned, the commonest of which in cancer of the lip are blebs and ulcers and, in order of frequency, small lumps, thickenings, cracks, warts, scabs, and, lastly, leucoplakia. It is thought that minor repeated injuries to the mucous membrane by the adhesion of cigarette papers, by clay pipes, or by a hot pipe stem, may lead to a precancerous chronic ulcer. The method of smoking, then, and not smoking itself, is incriminated. The commonest site of the growth is the lower lip, where it appears as an ulcer or a hard warty nodule on the red margin to one side of the mid-line, in the middle of the lip, or, most rarely, at the angle of the mouth. A striking fact emerges from a separate consideration of cancer of the lip in the two sexes. Whereas the ratio of lower lip to upper lip cancer is 27 to 1 in males, it is about 3 to 1 in females; that is to say, cancer of the upper lip, though a very rare disease in both sexes, is relatively more common in women. As a consequence of its slower rate of growth the results of treatment of cancer of the lip are better than those, for example, of cancer of the tongue. By modern operative methods there is a 60 per cent. survival rate of all cases, and an 80 per cent. survival rate of early cases, five years after treatment. In 90 per cent. of the cases in which recurrence takes place, this happens within three years of treatment. Therefore the patient who survives five years has a reasonable prospect of being entirely free from the disease. Although experience of treatment by radiation is less extensive, and sufficient time has not elapsed since its inception, it is justifiably assumed that the results are equal to, and possibly even better than, the results of surgical operation.

[1] Memorandum on Cancer of the Lip, Tongue, and Skin. Circular 1186. London: H.M. Stationery Office. 1931. (3d. net.)

Cancer of the Tongue

This disease is about ten times commoner in men than in women. Of a higher grade of malignancy, it is responsible for four times as many deaths as cancer of the lip, the mean age at death being about 61 years. During the decade 1911–20 the standardized death rate in males was higher than in the previous decade; by 1926 the rate had fallen, but since then there has been a tendency to rise. The site of election is at some point on the free border of the tongue, and, as in cancer of the lip, there is in a high proportion of cases some antecedent innocent condition. No experimental evidence has been brought forward in support of the contention that tobacco smoking causes cancer of the tongue, although two possible sources of chronic irritation, heat and the products of combustion, are inseparable from its practice. There is, however, a closer connexion with syphilis, for cancer of the tongue appears to be commoner in persons who have had a previous syphilitic lesion of the tongue. Leucoplakia, though one of the precancerous states of the tongue, may persist for many years without undergoing malignant change. Sharp or carious teeth, or badly fitting dentures, are obvious and avoidable causes of chronic simple ulcers which may become cancerous. The rapid spread of the disease to neighbouring lymph glands militates against successful operative treatment, only 20 per cent. of all cases surviving after three years. One of the chief factors in this low survival rate appears to be the length of time patients are willing to suffer from this disease before seeking treatment. Radiation, experience of which is limited, is being attended by favourable results.

Cancer of the Skin

The commonest variety of cancer of the skin is the rodent ulcer, of low malignancy and the most amenable to treatment of all cancers; the rarest is the highly malignant pigmented tumour arising usually in a pigmented mole or birthmark. In addition to these two, and resembling cancer of the lip in its mode of origin and course, is the ordinary cancer of the skin, or squamous epithelioma. Another important group is the one known to be associated with exposure to the products of combustion or distillation of coal, having a special predilection for the skin of the external genitalia of the male. The mean age at death is 66 for males and 68 for females. Precancerous conditions of the skin fall into two groups. On the one hand there are such chronic minor lesions as warts, pimples, scars, birthmarks, etc.; and, on the other, exposure to a variety of agents fully considered in the present memorandum. Mineral and shale oils are definite causes of occupational cancer, as, for example, mule-spinner's cancer and the paraffin cancers of the shale-oil workers in West Lothian. Tar residues and derivatives such as pitch, anthracene, asphalt, and creosote; together with lignite tar, gas-works tar, producer-gas tar, coke oven tar, and blast furnace tar, have all been shown to have carcinogenic properties. Another group of occupations in which skin cancer occurs in an unduly high proportion is that involving exposure to weather; and it appears that excessive exposure to sunshine, particularly in persons of fair complexion, is an etiological factor which cannot be ignored.

The Ministry of Health recommends that the group of cancers considered in this memorandum should be dealt with in each of its principal aspects—namely: (1) prevention or removal of environmental and other conditions known or suspected to be associated with causation; (2) curative treatment of abnormal conditions likely to develop the cancerous changes; and (3) surgical removal, by operation, radiation, etc., of the actual cancer.

TRACKING THE SOURCE OF INFECTION IN PUERPERAL SEPSIS

One of the most anxious and difficult problems connected with maternal mortality is to find the source of the infection in puerperal fever. Until substantial progress has been made in the elucidation of this question, it is impossible to attack, with any hope of success, the all-important subject of prevention. The work recently published by Dr. John Smith of the City Hospital, Aberdeen,[1] and noticed briefly in our columns on January 31st (p. 191), constitutes a step in progress which may have far-reaching consequences. Dr. Smith's report is based upon the study of 246 cases of puerperal infection which occurred in Aberdeen over a period of eight years. He agrees with the conclusion now reached, with practical unanimity, by all workers in the subject—namely, that in severe cases of puerperal fever the causative organism is nearly always the haemolytic streptococcus. If it could be established whence the organism comes, and how it obtains access to the genital canal of the parturient woman, the practical task of the obstetrician to exclude it would obviously be greatly simplified. The recent work of Leonard Colebrook and others suggests that anaerobic forms of streptococci are also capable of setting up acute puerperal infection, but the Aberdeen inquiry has, perhaps unwisely, ignored the anaerobic bacteria altogether. Further work will be required to show the relative importance of the latter organisms, and the sources from which they arise.

The haemolytic streptococcus, an aerobic form, is at the moment in the foreground of bacteriological work on puerperal fever, and the contribution made by Dr. Smith's latest research is that he has endeavoured to trace the source of the infection in twenty-one cases by careful and elaborate bacteriological investigation. In three cases the search failed entirely, and no explanation of the occurrence of the infection could be found. In the remaining eighteen cases it is claimed that the source from which the infecting organism sprang has been discovered. Briefly, the line of proof followed was to establish the morphological and serological identity of the organisms obtained from the uterus or the blood of the patient, with organisms obtained from those in attendance upon her during her confinement, or from an extragenital source of infection in the patient herself. The agglutination-absorption method of establishing serological identity, which was largely employed in this inquiry, is somewhat new, and perhaps it needs to be further tried out; but, with this reservation, the results obtained appear to be conclusive. In five cases the infecting organism was traced to the patient herself; in one of these the haemolytic streptococcus was traced to the patient's nose, in another to a septic focus on the finger; in three cases the *B. coli*, which was the sole infecting organism, was traced to the urinary tract or to the intestine of the patient. In the remaining thirteen cases the infecting organism was traced to one of the attendants—nurse, doctor, or student. In one of the thirteen a septic focus on the doctor's thumb was found; in the remaining twelve *Streptococcus haemolyticus* was traced to the nose or throat of one of the attendants. In all of these cases it would appear that the attendant was a "carrier," and had, at the time, no clinical manifestations of throat or nose infection. No information is given as to the clinical features of the twenty-one cases thus examined; which of these patients succumbed to the infection, and how many were clinically severe cases, is not stated. Evidently it is still necessary to urge that there should be the closest possible alliance between the laboratory worker and the clinician, and that bacteriological data cannot be fully comprehended, or applied in practice, unless accompanied by the relative clinical records.

The case thus presented from Aberdeen is by far the most conclusive we have yet obtained in favour of the view that droplet infection from the throats of carriers of the haemolytic streptococcus is a frequent cause of severe puerperal infection; that it is indeed by far the most frequent of all known causes. Without subscribing to the dictum that the throat is the "normal habitat" of this organism, its presence in the throat of large numbers of apparently healthy people is, by general consent, a frequent occurrence. Dissemination of the organism in coughing or sneezing, or perhaps even in normal talking, through droplet infection, will continually reinfect hands, instruments, and dressings which have been prepared by sterilization, and this would appear to constitute a grave and ever-present risk, not only to midwifery, but to surgical work of all kinds. The cases in which an extragenital source was found in the patient herself include three of pure *B. coli* infection in which the organism was traced to the intestines (two cases), and the urinary tract (one case). In one of them, a case of septic abortion, it is stated that no vaginal examination had been made "throughout the illness." These cases offer a striking proof of the importance of careful and thorough disinfection of the external genitalia, and they suggest that the methods in common use for this purpose are inadequate. In another case in this group the patient had a septic focus on her hand, and the report states: "there is every reason to suppose that the organism was conveyed from the hand to the genital canal." In only one case was the patient herself found to be a throat carrier of the *Strep. haemolyticus*.

The assumption that the results obtained in Aberdeen might be matched in most of our other large centres of population is not unreasonable. The grave warning conveyed is that in obstetrical work precautions must be taken to exclude droplet infection, at least as thorough as those adopted in surgical procedures; and

[1] Department of Health for Scotland. Report on Causation and Source of Infection in Puerperal Fever. Edinburgh: H. M. Stationery Office. 1931. (1s. net.)

that no reliance can be placed in midwifery practice on a single act of sterilization, such as the boiling of gloves or instruments, but that continual re-disinfection must be conscientiously carried out all through. In this connexion attention should be paid to the recent observations of Colebrook[1] and of L. P. Garrod.[2] The latter found that in laboratory tests " brilliant green " exerted the most powerful bactericidal action on *Strep. haemolyticus* grown in blood broth ; the former carried out an elaborate investigation of the best methods for sterilizing the bare hands, and also the hands gloved in rubber. The difficulty of freeing the skin of the hands from bacteria by any practicable method has been repeatedly demonstrated both in the laboratory and by clinical workers. On the other hand, Colebrook and others have now shown that the gloved hands can be cleansed and re-sterilized during attendance on a case with rapidity and certainty by very simple methods ; this observation forms an additional argument, if one be needed, for the routine use of rubber gloves in midwifery.

THE JOHN B. MURPHY ORATION

That distinguished American surgeon the late Professor J. B. Murphy of Chicago died in 1916, and, following a laudable custom, the American College of Surgeons established and endowed an annual Oration, to be delivered, in honour of his memory, for the advancement of surgical science. Last year the oration was given by Professor G. Grey Turner of Newcastle-upon-Tyne, on the occasion of the meeting of the clinical congress of the College at Philadelphia in October.[3] The authorities responsible for the choice of the orator showed great discrimination, for Professor Grey Turner has sat at the feet of his eponymous hero both in England and in America. Thus, unlike some of his predecessors, he has had the advantage of close personal knowledge of the manner of man Murphy was. Moreover, the orator is himself a kindred spirit, a surgeon of wide outlook and high ideals, his view of the surgical forest unobscured by the trees immediately surrounding him.

Murphy's name is a household word among surgeons, not only in English-speaking countries, but throughout the world, and although his famous button has been superseded by other means of intestinal union, its introduction marked a definite step in the progress of abdominal surgery, and as Professor Grey Turner says: " Its use introduced a new and successful era in gastro-intestinal operations, and did more than anything else to place this branch of surgery on a secure footing." Not only in the advance of abdominal surgery did Murphy play a great part ; he illuminated and improved the practice of surgery in many directions, notably in the treatment of bone and joint diseases. His bold procedures for the relief of ankylosis of large joints, such as the knee, were ahead of his time, and it is only since the war that other surgeons have reached, in this respect, the position to which he had attained. Like many other American surgeons, Murphy had studied the methods of German teachers and adopted the type of clinical teaching which has long been in vogue in Germany generally, and in its highest perfection in Vienna under von Billroth. Professor Grey Turner, however, is fully impressed with the superiority of the British system, of which the merits were recognized in the Flexner Report of 1912. The value of early and free contact between the student and the actual manifestations of disease cannot be overestimated.

The orator chose for the title of his address " Ideals and the art of surgery," illustrating his theme by discussing some present-day problems and their possible solutions. Referring to the old question of when to operate for appendicitis, he declared that there was no medical treatment of the condition, but that Murphy's dictum " Get in quick and get out quicker " still held good. This must not, however, be taken to mean that the abdomen should be recklessly opened for diagnostic ends or that operative procedures should be scamped for the sake of saving time. Professor Grey Turner, in considering the ideals for which he would strive, surveyed some of the principal fields of major surgical practice. We welcome his protest against undue despondency in regard to malignant disease. He says that so pessimistic is the attitude of some surgeons and physicians, that many members of the profession are deterred from advising intervention. In his belief, attention has been too much diverted to methods of irradiation, which have not yet been sufficiently elaborated to take the place of the knife. Until we have a much greater experience of the capabilities of radiation as a cure of malignant disease, thorough surgical treatment still holds the field as the only hope of cure in many cases of grave malignant disease. Professor Grey Turner showed from the records of his own cases that " when the efforts of the surgeon have been well planned and *have been sufficiently thorough*, the results have often been commensurate with the sacrifice which the patient has been led to make." Cases such as some of those he describes, in which dissemination had not already occurred and the tumour and the affected glands were adequately removed, and which have survived gastrectomy for varying terms of years, give good grounds for trust in adequate surgery. Still more hopeful are cases of rectal and colonic cancer when the sphincter can be preserved and the patient spared the horrors of a colostomy.

So strongly does Professor Turner feel on the question of the treatment of tuberculous glands that in order to drive home his argument to his readers' and hearers' convictions, he has reproduced a sketch of a tombstone, with the inscription " J. Tubercle, Not Dead, But Sleepeth." He holds that indiscriminate removal of tuberculous glands is objectionable, seeing that there are, in his opinion, two main sources of infection: one which is entirely local and arises in connexion with the tonsils or

nasopharynx, and another, a primary infection of the mesenteric or mediastinal glands. Excisions in the first group allow good hope of permanent cure; in the other, the remaining "not dead, but sleeping" tubercle bacilli reassert themselves and awake in new and often fatal manifestations. He ended his address with a suggestion that his selection for the honourable post of Murphy Orator might be taken as a compliment to the provincial school of surgery to which he belongs, for he does not forget that Murphy once said that the best surgery is not all done in the biggest cities. We are within a year of the celebration of the centenary of the Association, which was founded by provincial physicians and surgeons when our art was still flourishing in places other than the metropolitan cities. If subsequently centripetal forces prevailed for a time, surgery is nowadays enriched in abundant measure by the contributions of the provincial schools.

UNDULANT FEVER IN THE UNITED STATES.

Probably no other disease has attracted such attention during the past few years from the clinician, the public health official, the veterinarian, and the bacteriologist, as undulant fever. The disease appears to be world-wide in its prevalence, and is showing an increase—whether apparent or real it is difficult to say—that is formidable. In the whole of the United States 24 cases were recognized in 1925; four years later 1,305 cases were detected. A report by Hardy and his colleagues[1] now deals with 375 cases occurring in the single State of Iowa. Besides drawing attention to the frequency of undulant fever, this report is of particular interest for the light it throws on the epidemiology of the disease. Iowa is a State in which cattle-raising and hog-raising are the two main industries. Contagious abortion is rife in both these animals. There are very few goats, and herds of sheep are scattered. Under these conditions it is not unreasonable to expect that most of the undulant fever in man is of bovine or porcine origin. The bacteriological evidence confirms the truth of this surmise. The causative organism was isolated from the blood stream of 48 patients; one patient had a double infection, so that 49 strains were recovered; of these, 35 proved to be of the porcine, and 14 of the bovine, type of *abortus*. The greater proportion of porcine strains isolated cannot, it is pointed out, be taken to mean that infection of porcine origin is commoner than of bovine origin, because, in practice, positive blood cultures are very much more frequent in patients infected with the porcine than with the bovine strains. From a general review of all the information available it is considered that the two organisms are about equally responsible for the undulant fever morbidity in Iowa. Studying the probable modes of infection, the authors classified their cases into three groups: (1) Those without direct contact with live stock or carcasses. Of the 125 patients in this group, 51 per cent. were males and 49 per cent. females, the majority living in small towns or cities; and since all the eight strains of Brucella recovered were of the bovine type, it is probable that infection occurred through the consumption of raw dairy produce. (2) Rural cases having direct contact with live stock. Of the 169 patients in this group, 96 per cent. were males and only 4 per cent. females. Practically all patients had contact with both cattle and hogs. The age distribution was from 15 to 55 years. Twenty-nine strains of Brucella were isolated; of these 24 were of the porcine and 5 of the bovine type. Infection was probably derived about equally from cattle and hogs. Most of the infections derived from cattle could be explained by ingestion of raw dairy products; those derived from hogs appeared to result from direct or indirect contact with infected animals, the portal of entry presumably being the skin. (3) Urban cases having direct contact with live stock or carcasses. This group comprised 40 patients, all males, 37 of whom were packing-house employees working in the hog division. Of the ten strains of Brucella isolated, all were of the porcine type. Infection apparently occurred by direct contact with fresh tissues of diseased hogs. Clinically the cases of porcine infection tended to be more severe than those of bovine infection. Most of the patients had an intermittent fever, associated with lassitude, weakness, sweating, anorexia, chilliness, and loss of weight. The average duration of the disease was about three months, but the ensuing debility often lasted much longer. The case mortality was 3 per cent. It is interesting to note that pyrexia of the classical, undulant type was only occasionally seen; this circumstance probably accounted for the frequent failure of the attending physician to suspect the true nature of the illness. Erroneous diagnoses were frequent; the commonest were typhoid fever, influenza, and tuberculosis, but suspicion was often cast on the cardio-vascular or genito-urinary system. Abdominal symptoms were often misleading, and in this connexion the authors state that Simpson had a record of twelve appendicectomies and two cholecystectomies performed on cases of undulant fever. It is clear that the real frequency of this disease will not be ascertained till the practice is universally adopted of examining the blood serum of all patients who are suffering from an undiagnosed pyrexia.

THE FIRST INFANT WELFARE CENTRE

The first "infant consultation" in this country was held at St. Marylebone Dispensary, in Marylebone Lane, on March 14th, 1906, and the pride of priority was evident in the enthusiastic gathering held, on April 29th, at the dispensary, under the chairmanship of the Mayor of St. Marylebone, to celebrate a quarter of a century of achievement. Miss Susan Lawrence, M.P., Parliamentary Secretary to the Ministry of Health, came to give the occasion official blessing. She referred in particular to the rheumatism clinic, the ante-natal clinic, and the clinic for the pre-school child, as examples of the pioneer work done at St. Marylebone, which the Ministry desired to see extended to every part of the country. The marked improvement in the figures relating to infantile mortality, she said, had come about as the result of intensive propaganda, and, given the same determination, this outstanding success might be repeated with the child of between 2 and 5, and also in the elucidation of the problem of rheumatism and its treatment. Dr. Eric Pritchard, who was responsible

for the first "infant consultation" twenty-five years ago, and held the office of director of the clinic from 1906 to 1922, gave some reminiscences of the early days, and mentioned the names of a number of workers, some of them no longer living, who courageously faced the problems attending a new venture. In the early days the two principal matters of concern were infant mortality and tuberculosis. It was the strong belief of those who started the clinic that infant mortality was in very large measure due to lack of knowledge, and therefore the "infant consultations" were started, the idea being that the voluntary health visitors should encourage mothers to bring their babies to the dispensary, where they could be medically examined, and where good advice could be given as to care and feeding. It was, in effect, instruction in mothercraft, although that word had not then been coined. The clinic instructed the mothers to arrange for longer intervals between feeding, to give up the stiff binder and the iniquitous "comforter"; it introduced dried milk, and exact methods of measuring food, and it also arranged competitions for mothers, and encouraged them in various ways. What St. Marylebone did was quickly followed by other London boroughs and provincial towns, not always, Dr. Pritchard said, with proper acknowledgements to St. Marylebone, though the indebtedness to Continental institutions, particularly the French ones, was freely admitted. The great thing was, however, that the work was done, and that a ball was set rolling, which was rolling still, and still gathering momentum. Dr. Charles Porter, medical officer of health for St. Marylebone, referred to the world-wide extension of the movement which had its origin in Marylebone Lane. To-day, in the Far East and the Far West, infant welfare centres were in operation, and were doing unconscious homage to Eric Pritchard. To-day, the infant mortality rate was only half of that of 1906. Mr. W. McAdam Eccles, senior honorary consulting surgeon to the charity, in proposing a vote of thanks to Miss Lawrence, referred to the education of mothers which had taken place during the quarter of a century, especially in regard to the proper feeding of children and the provision of fresh air.

ENTERIC FEVER IN 1929-30

The recently published January issue of the Epidemiological Report of the Health Section of the League of Nations is devoted to a consideration of the morbidity and mortality of typhoid and paratyphoid fevers throughout the world during the past two years. A graph of the trend of enteric fever from 1922 to 1930 shows that no pronounced change in the incidence of the disease has occurred during this period in Germany, England, and Poland, apart from a slight decline in March and April, which are the months of lowest typhoid morbidity. In the United States there has been a steady decrease in the incidence of typhoid, the disease being most prevalent in the southern States. In France there has been a distinct drop in the frequency of enteric, from 1928 to 1930, the figures being 9,762, 7,280, and 6,408. In Italy the number of cases has remained stationary. In the Soviet Union, on the other hand, there was a great increase in typhoid morbidity in 1929, especially in the Ukraine and Siberia. In 1930 a considerable epidemic due to defective sewerage occurred in Leningrad. As regards typhoid mortality there has been a universal and very striking decline during the last ten years, except in Spain and Hungary, where the reduction has been least marked. The cause of this decline is mainly to be found in the general improvement of the water supply, and to a certain extent in the antityphoid inoculation of a large proportion of the male population during the war, and to the continuance of this practice in countries with military conscription. It is noteworthy that since the war, as is illustrated by experience in Pforzheim, Lyons, Paris, and Hamburg, both the incidence and the case mortality of enteric fever in women, among whom inoculation had not been carried out, have been higher than in men. A table of the case mortality of enteric fever in various countries during the period 1923 to 1930 shows such wide variations as 2.8 per cent. in Lithuania and 25.4 per cent. in Switzerland. So marked a difference is obviously not due to variations in the pathogenicity of the typhoid bacillus, and can be explained only by the more careful system of registration of deaths carried out in Switzerland. International comparison of the case mortality of enteric fever is further vitiated by the fact that in many countries no differentiation is made in the statistics between typhoid and paratyphoid fever. That the higher death rate among young persons is a very general phenomenon is shown by statistics from England and Wales, Massachusetts, the Philippines, and Siberia.

A EUGENIC EXPERIMENT

Experiments in eugenics with the human species are exceedingly difficult to make or to control, and cannot be conclusive until after a very long period of time. Hence, some degree of importance attaches to any suggested practical method for bringing about selective breeding on a considerable scale, and observing its results. In this respect an article in the April number of the *Eugenics Review*, entitled "Positive eugenics in practice," may be read with interest. It is by M. Alfred Dachert, and professes to give "an account of the first positive eugenic experiment." This may be held to be too high a claim; but M. Dachert is the originator and director of a garden city enterprise at Strasbourg of a novel character (*Les Jardins Ungemach*); and what he has there been able to accomplish is certainly worthy of notice and suggestive for further activities of an analogous kind. The essential feature of the experiment is not, of course, the planning and building of an estate on certain lines, but the selection of the people who are to inhabit the houses. Incidentally, it is interesting to note that the author found his two chief model garden cities in the East—the Manchu town of Peking, "the model for all the rest," and New Batavia, in Java, "probably the most remarkable of our time"—and that he concluded that in Europe such cities did not assist, as they should, the progress of the human species, because "dwelling there I saw old maiden ladies, widows, and sundry others who had been chosen by the merest chance." It was determined that in *Les Jardins Ungemach* the laying-out and regulation of the estate and its houses should be such as to promote the well-being of large families, each house being so planned as to avoid all unnecessary work for a young housewife who is expected to have children, but cannot

afford the help of a servant ; and that the inhabitants should be chosen, not from the point of view of their being good paying tenants, but for their human qualities. The tenants desired were " young couples in the best of health, comely and vigorous, and who really wanted children." Careful means were taken to find such couples, and success has been achieved. The Foundation has been in existence for seven years, and there are now 140 houses, with sixty others in building. In nine cases the tenants have had to be removed because the families were not forthcoming. Some other families have removed to better-class dwellings, or built their own houses elsewhere. There are no public-houses on the estate, and drunkenness is unknown. The police have never had to be called in during the seven years. There is a system of visitation of all the houses annually, and some sort of competition for cleanliness and good management. Only once has a rent been unpaid, and there are many signs of increased well-being and social and economic progress. M. Dachert gives statistics of the comparative birth rate and death rate in *Les Jardins Ungemach* and in the town of Strasbourg. The contrast in the figures is certainly striking, but they are not really comparable. Nevertheless, though the number of persons is small, and though comparisons may be made and conclusions drawn which are not wholly warrantable, this experiment is well worthy of attention.

CHINESE QUARANTINE SERVICE

After years of patient plodding by a small band of Chinese and foreign medical men the National Quarantine Service of China was established in July, 1930, and the work of giving practical effect to its regulations was begun at the various ports of the country. These quarantine regulations were promulgated by the Chinese Ministry of Health with the help of the League of Nations Health Service. The headquarters of the quarantine service are at Shanghai, and cognate health services have been inaugurated and administered under the directorship of Dr. Wu Lien-Teh, whose report is now before us.[1] The first part deals with cholera investigations in Shanghai during the summer of 1930. The account given is notable for the additional observations it brings to bear on the difficulties of diagnosis between true cholera and paracholera. This has greatly troubled all public health authorities from the Hedjaz eastward (vide *British Medical Journal*, 1930, December 20th, p. 1052), for while it is now a well-established fact that even true and agglutinable cholera growths may be met with where vibrio forms are not conspicuous, or are absent, on the other hand other organisms, chiefly the *B. faecalis alcaligines*, may appear quite vibrio-like in stained preparations, and this bacillus is as avidly aerobic as the *V. cholerae*. In Shanghai, vibrios were found which closely resembled the true *V. cholerae* in all respects except agglutinability. This report, therefore, in stating that these paracholeraic organisms differ only serologically from *V. cholerae*, confirms the Medical Research Council's findings that absolutely reliable diagnoses can be obtained only by cultural methods. The investigations made by Dr. Wu and his staff are a good contribution to the data that are being collected in dealing with a subject which is of great importance in the management of choleraic and diarrhoeic outbreaks in the densely crowded areas of Oriental cities. In Shanghai for years past the problem of cholera has been an acute one, and has grown more so with the development in size and population of this, the greatest city of the East. That the Chinese community of Shanghai is thoroughly alive to the menace of cholera is shown by the unusually large number of clinics and hospitals for the care of patients suffering from summer diseases. A fortunate feature is the amenability of the Chinese people to the requirements of modern epidemic management. Thus, no resistance was offered to an active anticholera vaccination campaign being carried out universally, and no fewer than 537,034 inoculations were done. This no doubt was an important factor in limiting the spread of the 1930 epidemic to 128 cholera cases (including one carrier) which were recorded. The activity of the Central Cholera Bureau medical officers is shown by the fact that they collected samples of faeces from public latrines, and took notes of the persons examined, so that in case of positive findings further investigations could be made ; 1,200 specimens were submitted to laboratory examination from this source, in addition to 400 from hospitals. The report includes a historical sketch of the cholera epidemics which have visited Shanghai from 1820 to the present time, and a series of tables summarizing the details and results of all investigations is added. There is also a paper by Dr. C. L. Park, chief of the Epidemiological Division, League of Nations Health Section, on the quarantine needs of the port of Shanghai. The Chinese Ministry of Health is supporting all these projects.

[1] *Publications of the National Quarantine Service, Republic of China*, Series I. Edited by Dr. Wu Lien-Teh, M.D., LL.D., D.Sc. February 10th, 1931. N.Q.S. Office, 2a, Kiukiang Road, Shanghai.

THE L.C.C. AND ANTE-NATAL CARE

In discussing the report of the Departmental Committee on Maternal Mortality and Morbidity, the Central Public Health Committee for London draws attention to two recommendations which are of great importance to the County Council: (1) that a satisfactory scheme of ante-natal care must be based upon the principle that the persons responsible for ante-natal supervision should be the persons responsible for attending labour ; and (2) that the type of organization which best meets the need for systematic ante-natal care is probably the hospital ante-natal clinic, with its specialist officers, pathological laboratory, and facilities for special treatment, both in-patient and out-patient. Each metropolitan borough now has its ante-natal clinic, either municipally provided or voluntary, but the medical superintendents of the transferred hospitals have made increasing efforts in the past few years to obtain control of the ante-natal care of the patients who were booked for delivery in their wards. At the present date fifteen general hospitals in London take entire responsibility for such women as can be induced to attend (in many of the hospitals, practically all the women). At four hospitals the medical staff see mainly abnormal cases referred to them from the borough ante-natal clinics, but are increasing their supervision of normal routine cases ; and at other hospitals and institutions which contain maternity wards, but at which little

or no ante-natal work is done, the patients, or some of them, attend the borough ante-natal clinics. It is added that the standard at the hospital ante-natal clinics appears in almost every case to equal or exceed that recommended in the Departmental Committee's report. The attendances in most instances reach forty to sixty a session, and are putting a great strain on the available accommodation, which may have to be increased.

THE SOCIETY OF APOTHECARIES' ROLL OF BIO-PHYSICAL ASSISTANTS

We publish this week as a Special Supplement the complete list of names on the *Register of Bio-Physical Assistants*, revised to March 31st, 1931. It may be well to recall here once again that in 1928 the Representative Body of the British Medical Association drew attention to the need for the registration of competent and suitable lay persons to whom medical practitioners could with confidence send their patients for electrical treatment and actinotherapy. A small committee of experts was formed to draw up a practical scheme, which, after presentation by the Science Committee, was approved by the Council of the Association. In January, 1929, the Court of the Society of Apothecaries of London decided to adopt and to further this scheme for granting diplomas, after examination, to bio-physical assistants, and for the establishment of a register. Regulations were drawn up, and the first *Register of Bio-Physical Assistants* was issued in book form a year ago under the Society's direction. Our purpose in publishing the revised edition of this register is to make it widely known to members of the medical profession in a form convenient for ready reference. The entries in Part I are arranged in alphabetical order, with postal addresses; in Part II the names are re-grouped geographically. Subject to the reservation in respect of blind masseurs and blind masseuses, those whose names appear in the general and local lists printed in this week's Special Supplement have been approved by the Society of Apothecaries as persons "competent to dispense the direct current, ionization, faradic currents, sinusoidal currents, diathermy, high-frequency currents, light and heat, and ultra-violet light." Since the British Medical Association was primarily responsible for the setting up of the register, we hope that members will preserve this Supplement and send their patients who require treatment by light and electricity to technicians holding the Society's diploma.

BRITISH ASSOCIATION CENTENARY

The British Association for the Advancement of Science has now issued a preliminary programme for the centenary meeting to be held in London from September 23rd to 30th, under the presidency of the Right Hon. J. C. Smuts. The clause in the statutes of the Association stating that there should be "no invasion of the ground occupied by other institutions" probably accounts for the fact that this is the first time in the history of the Association that London has been chosen for the annual meeting. General Smuts will succeed Professor F. O. Bower as president, at the inauguration ceremony on September 23rd, in the Albert Hall, where the Faraday centenary exhibition will be held concurrently. In the evening of the same day General Smuts will deliver his presidential address in the Central Hall, Westminster; for admission a special ticket will be required. Evening discourses to members will be given by Professor W. A. Bone and Sir Peter Chalmers Mitchell on September 24th; by Sir Arthur Keith and Sir Oliver Lodge on September 26th; and by Sir William Hardy and Sir James Jeans on September 29th. Dr. G. Thilenius will give the Huxley Memorial Lecture before the Royal Anthropological Institute on September 29th; members of the British Association are invited to attend. Certain subjects in the programmes of the Sectional meetings will be of special interest to the medical profession. These include a discussion on the chemistry of vitamins, on development and embryology, on the physiology and psychology of work, on the biological nature of filterable viruses, on the physiological basis of sensation, on the psychology of mental defect, and on child guidance and school clinics. Visits will be paid to York, where the Association was founded, and to Down House, Darwin's home from 1842 to 1882, which has been under the care of the Association since 1929. During the week before the meeting there will be a geological excursion to East Anglia. Special arrangements have been made with the railway companies, hotels, and boarding-houses, for the transport and accommodation of members visiting London.

RESEARCH FELLOWSHIPS IN TUBERCULOSIS

The Dorothy Temple Cross Research Fellowships in Tuberculosis for the academic year 1931–32 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 6th. The object of these Fellowships, as defined in the trust deed, is to give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." Candidates must be British subjects, and must possess suitable medical, veterinary, or scientific qualifications. They must also be able to produce satisfactory evidence of their ability to make good use of the opportunities offered by the Fellowships. The Fellowships will preferably be awarded to candidates who wish to conduct their studies or inquiries outside the confines of Great Britain. They will, as a rule, be awarded for one year, but in special cases may be renewed. The value of the Fellowships will depend in each case upon the standing and qualifications of the candidate, but will not be less than £300 per annum, with travelling expenses in addition. It may also be possible to award a Senior Fellowship of considerably greater value to a specially well-qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis, at a chosen centre of work in another country. Further particulars and forms of application are obtainable from the secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W.1.

On May 5th the King conferred the honour of knighthood on Mr. Henry L. Martyn, C.V.O., F.R.C.S., Surgeon Apothecary to His Majesty's Household at Windsor, and invested him with the insignia of a Knight Commander of the Royal Victorian Order.

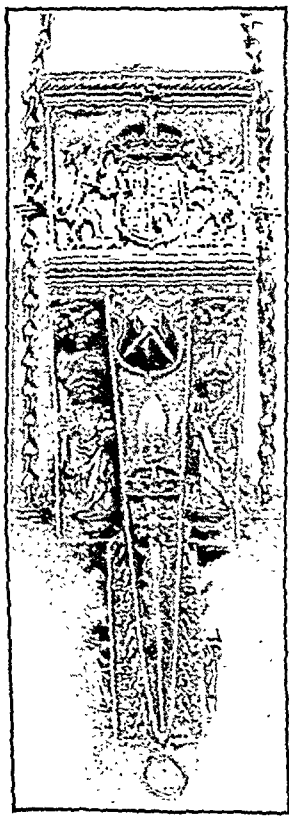
Nova et Vetera

A BARBER-SURGEON'S INSTRUMENT CASE OF THE TUDOR PERIOD

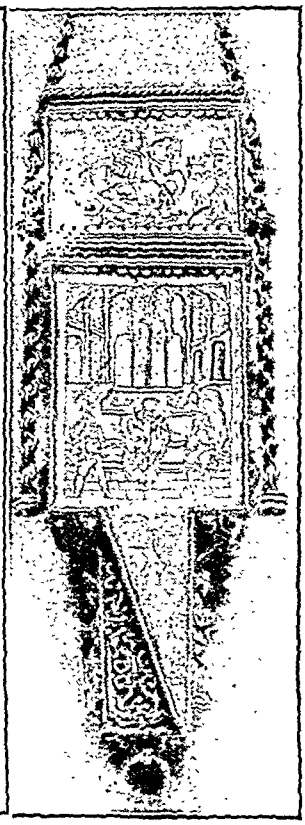
A surgical instrument case finely wrought in silver, dating from the early part of the sixteenth century and bearing evidence of its association with a Tudor king and the Barbers' Company of the City of London, is a relic of more than ordinary interest. The early history of this case, which was exhibited at the Vicary Lecture delivered by Professor G. E. Gask in November last, is unknown, but apart from its historical associations its beauty as a specimen of the goldsmith's craft merits some detailed description.

It is made throughout of silver, which is gilded in some parts, and measures seven and a quarter inches in length, two and a quarter inches by two inches in section at the top, and slightly tapering at the base, from which projects a narrower part of a similar section. The cover or lid is retained in position by the lining of wood and leather which finishes above the lip of the body, thus forming a bezel over which it fits. Two chains, secured at the ends by a ring held in the mouth of a lion's mask fixed on each side of the lower section, again pass through other rings attached to the cover, and so hold this in position, while allowing it to be raised to remove the instruments when required.

The whole case is richly decorated in high relief, and on the front of the cover bears the royal arms of Henry VIII enamelled in colour. The supporters—a greyhound and a dragon—were those used by Henry VII and his successor until 1525, the whole being surmounted by a royal crown.



FRONT.



BACK.

The front of the case bears a shield enamelled in colour with the arms of the Barbers' Company, a chevron between three fleams argent, that were granted to the Company by Edward IV in 1462. On either side are the figures of St. Cosmas and St. Damian, the patron saints of the Company, the former holding a urine flask and the latter a drug pot. In the centre, below the shield, is a spatula surmounted by a rose, crowned—a cognizance that was granted to the Surgeons' Guild by Henry VII in 1492. When Henry VIII incorporated the Fraternity or Guild of Surgeons with the Barbers' Company, the arms of the two bodies were united, but when the Companies again separated in the time of George II, the Barbers retained the charges which originally belonged to the Fraternity or Guild of Surgeons.

The back of the case is also richly ornamented, the lower part being engraved with a representation of the martyrdom of Thomas à Becket, and the cover with a spirited rendering of St. George slaying the dragon, each panel having a corded frame. The lower narrow section is divided diagonally with a corded relief, and engraved with arabesques on one side and a scroll relief on the other. The sides of the case are also elaborately decorated with engraved scrolls and grotesques, and in the lower part stand two niched figures in high relief, one representing St. Catherine holding a sword with a wheel at her feet, and the other St. John carrying a chalice. The inclusion of these saints in the scheme of decoration may have been due to their association in some way with the owner, or it may have a purely symbolical significance. There is little known to connect St. Catherine with surgery or the art of healing, but, according to tradition, she was regarded as the patroness of centres of learning, and consequently of universities. There are, however, several legends associating St. John with medicine, and in the time of St. Augustine it was customary to place written words from his gospel on the heads of the sick to aid their cure, or to write certain texts on parchment and wear them round the neck. In the early part of the seventeenth century Pope Paul V ordered the clergy, when visiting the sick, to place their hand on the head while reading the gospel of St. John. There is also an ancient legend that he was once given a chalice containing poisoned wine, and that when he blessed it the poison came forth in the form of a serpent.

The top of the cover is surmounted with the Tudor rose in red enamel on silver and gilt, supported by the greyhound and dragon, and the royal crown is repeated. The bottom of the case is decorated with a lion's mask holding a corded ring. The interior is lined with wood and leather, with receptacles for six instruments, which, judging from their shapes, probably consisted of a large scalpel, forceps, scissors, and lancets. The silver chains meet at the top in a ring for attaching the case to the girdle, and the whole fits into a larger leather case incised with a decorative design.

That this case was made not later than 1525 is evidenced by the fact that the greyhound as a supporter of the royal arms was only used by Henry VIII until that year, when it was superseded by the lion. To whom it originally belonged can only be a matter of conjecture, but there is little doubt that it was a royal gift, probably made by Henry VIII to one of his surgeons. He may have presented it to Marcellus de la More, whom he first appointed as surgeon to his person in 1510, and who was later made Sergeant of the King's surgeons in 1513. In a contemporary record he is described as "the King's surgeon and granted 40 marks a year during his pleasure." On the other hand, it may have belonged to Thomas Vicary, who was the direct successor of Marcellus de la More, and who was appointed chief surgeon to the King and Sergeant to the King's surgeons in 1528. When Henry VIII presented the Company of Barber-Surgeons with their charter in 1540, Thomas Vicary was the Master of the Guild, and in the picture painted by Holbein to perpetuate the occasion he is represented as kneeling before the King and receiving the charter from his hand. Subsequently Vicary held the appointment of surgeon to King Edward VI, Queen Mary, and Queen Elizabeth, and died in 1561.

The case may have been intended for use on ceremonial occasions only, as when the Masters of the City livery companies took part in processions on State celebrations it was customary for each to carry an emblem of his craft, and certainly nothing fitter could have been devised to symbolize the art of surgery. But, whatever its story, it is to be hoped that this beautiful and interesting historical object will find a permanent home in one of our museums.

Royal College of Surgeons of England. C. J. S. THOMPSON, M.B.E.

INCOME TAX

REASSESSMENT OF PROPERTIES, 1931-32

Income from property is comparatively steady, and therefore the Income Tax Acts provide, as a rule, that assessments made for any particular year shall, so far as the fixing of the annual value of the property is concerned, be continued for the next year. The Finance Act of 1930, however, provided that all properties in Great Britain should be revalued for income tax purposes, so that revised assessments under Schedule A could be made for 1931-32. The usual forms calling for particulars of rents, terms of tenancy, etc., were accordingly issued, and it is understood that the authorities have now prepared fresh assessments and are issuing, or shortly will issue, notices of assessment. These notices will set out particulars of the new valuation of the gross income from the properties and the allowances made therefrom to meet the cost of repairs and other maintenance charges. It is understood that objections must be lodged within twenty-one days from the issue of the notice, but, judging from past experience, a rigid insistence on that time limit is not likely to be pressed if there are any circumstances rendering compliance more than ordinarily difficult. The giving of a notice of objection does not indicate a necessity for any formal appeal; if the objection is accompanied by a reasoned statement of the grounds on which the assessment is considered to be excessive, the inspector of taxes, or some member of his staff, will no doubt be quite willing to discuss the merits of the objection, either by correspondence, or, perhaps with greater convenience to both parties, at a prearranged interview. The importance of avoiding any over-assessment is increased by the fact that the new valuation will last for five years, and a few notes on the matter may be welcome at this stage.

Where the premises are rented, the amount of the rent naturally determines the annual value for taxation of the income—unless a premium was paid for the lease or the property has been improved by the tenant—and the tax is ultimately borne by the landlord and not by the tenant. We therefore propose to refer to such properties only to the extent necessary to make clear an important consideration that arises on the valuation of property occupied by the owner—a class which includes many, if not most, of the premises occupied by medical practitioners. At the present time many rents are still affected by the Rent Restriction Acts. As our readers will remember, that series of enactments was passed to protect tenants from the exorbitant rents which the post-war famine in domestic accommodation might have enabled some landlords to demand and obtain. The effect may briefly be stated as preventing the raising of rents of premises to which the Acts apply, by more than 40 per cent. over the pre-war rental. (The Acts do not apply where the pre-war rent was £78 and above in the provinces, or £105 and above in the metropolis.)

In process of time premises originally within the Acts have, by compliance with one or other of the conditions exempting them from the scope of these Acts, ceased to be let under "rent restriction" conditions, and the additional rent which the owner has been able to obtain has been more than the 40 per cent. previously payable. Consequently, when the value of premises occupied by the owner is in question, and the obvious course is followed of comparing the property with similar premises which are let at rentals, the difficulty met is that the similar properties may show widely divergent rentals. For instance, suppose the value to be ascertained is that of a practitioner's professional premises, which on a pre-war basis would have let for £60, it may be found that they are reasonably comparable with one house now let under rent restriction conditions at £60 + 40 per cent. = £84, with a pre-war house not under such conditions and let at £95, and also with a house built at post-war prices and let at £120. In such circumstances, and they are by no means uncommon, it is obviously important to the practitioner to know which of the three classes of property supplies the correct test of value. Fortunately, the income tax authorities are apparently willing to follow the example of the rating authorities and accept the "pre-war rent plus 40 per cent." as the appropriate standard of comparison. Where, therefore, the gross value shown in the notice of assessment materially exceeds a valuation calculated on that basis the owner should give notice of objection and state his reasons for assigning to the property the pre-war rental on which his own, smaller, gross value is based. It may be the case that the property in question was built after the war, so that there was no direct pre-war valuation of that particular house. In such circumstances the owner will be well advised to ascertain, if possible, the pre-war rents paid for somewhat similar properties, and claim that his own premises should be valued at a 40 per cent. increase on these rents. Many post-war properties were built at a time when building costs were abnormally high, and any computation of rental value by reference to, say, 5 per cent. on the capital cost is likely to yield a result considerably greater than that obtained by the method indicated above. There is a certain plausibility in the argument that if, say, £2,500 has been invested in acquiring a property then the gross income might reasonably be assumed to be 5 per cent. on £2,500 = £125, but any such argument should be countered by pointing out that in the first place the capital cost was inflated, and in the second that the 40 per cent. addition to pre-war value is a basis which is universally accepted in such cases.

It may occur to some practitioners that as, say, one-half of the Schedule A assessment is normally treated as a payment of rent for the professional part of the premises when calculating the profits of the practice, the final result of an alteration in a Schedule A assessment is not substantial. In certain cases this is correct, but one or two points must be considered: one is that the relief to earned income does not apply to assessments under Schedule A; another, that Schedule D liability is based on the previous year's profits, so that if an increase in the Schedule A assessment is made for this year the whole increase is a net addition for 1931-32, because the deduction for Schedule A would be one-half, or some other fraction of the old assessment for 1930-31.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY

ANNUAL GENERAL MEETING

The annual general meeting of the London and Counties Medical Protection Society was held at Victory House, Leicester Square, on April 29th, under the chairmanship of the president, Sir JOHN ROSE BRADFORD, Bt. The report of the council, which was presented, stated that the society had done another year of useful work, with a substantial increase in membership. The number of new members elected was 796, and the membership now stood at 12,275. The number of applications for advice and assistance from members had been 1,171, as compared with 1,079 the year before. In the majority of cases satisfactory results had been obtained without litigation, and the issue in most cases in which litigation had occurred was satisfactory to the members. A larger number of actions than usual had been brought by and against members, but the greater part of them were settled

without reaching a hearing in court. The solicitors' report stated:

"*X* rays should be a word ever present in the minds of all members of the profession when dealing with injuries. . . . The society is still seeking the opportunity of a test case which may decide to what extent the report of a radiologist (medically qualified) will protect a surgeon or a general practitioner. Whilst on this subject, whatever the decision of the courts may be, we feel we should again repeat our warning of last year, that members of the profession must not rely upon the report of a radiographer (without medical qualification)."

The financial statement of the society showed its income last year to be £12,280, its expenditure £10,268, and its accumulated funds, at the market value of the investments, £47,829.

Sir JOHN ROSE BRADFORD said that a gain of 800 members in the year, while gratifying in some respects, was not very satisfactory when it was remembered how large a number of practitioners still remained outside any defence organization. A member of the council of the society, listening week by week to the cases which came before it, might be excused if he ran away with the idea that the one thing which happened to medical men in their relation to the public was to have charges brought against them. That would be a gross exaggeration, but the number of cases in which charges were brought, often with very little substance, showed clearly to anyone connected with work of this kind the absolute necessity for every member of the profession, no matter how secure he might imagine himself to be, to belong to a defence society. The president referred also to the trouble which constantly arose through members, when involved in prospective litigation, taking action first of all on their own account before communicating with the society. Finally, he spoke of the severe losses which the society had sustained during the year in the deaths of Dr. J. H. Stowers, who had served the council indefatigably, Mr. H. W. Carson, a new member of council from whom much had been expected, and Mr. A. G. R. Foulerton, for many years financial secretary.

Dr. C. M. FEGEN proposed the re-election of Sir John Rose Bradford as president, remarking that Sir John was much more than a distinguished figurehead; he interested himself in every detail of the society's work.

Sir John Rose Bradford was re-elected unanimously and with acclamation, and the re-elections also took place, with similar compliments, of the vice-presidents, the retiring members of council, the treasurer (Dr. Fegen), and the general secretary (Dr. Hugh Woods). It was announced that it was not intended for the moment to fill the position of financial secretary vacant by the death of Mr. Foulerton, but that a committee of the council was being set up with a view to going into the whole question of the organization of the society in this respect.

Scotland

Dr. William Smellie's Tombstone

Under the presidency of Dr. James Hendry a ceremony took place at St. Kentigern's Old Churchyard, Lanark, on April 25th, when the renovated memorial stone on the grave of Dr. William Smellie was unveiled by Professor Munro Kerr of Glasgow University. In the course of an address Dr. J. Haig Ferguson, President of the Royal College of Surgeons of Edinburgh, said that Smellie, who had been described as the greatest of British accoucheurs, died in 1763 at the age of 66, and the Edinburgh and Glasgow Obstetrical Societies had combined to renovate and restore his tombstone, which was falling into disrepair. It was well, in the rush of modern life, to pause occasionally and consider how their professional fathers dealt with the problems of their time. William Smellie had been the most prominent and best-equipped teacher of obstetrics in his day, and, according to a contemporary, was everywhere beloved for his benevolent disposition, as well as for his judgement and understanding. It was impossible to exaggerate the far-reaching influence of a teacher like Smellie, whose principles had resulted in benefits which were apparent even to this day. It was remarkable that this young Scottish doctor in homely country practice had evolved ideas which enabled him to introduce into London better methods of teaching midwifery than any that were then known. Smellie's methods and results were comparable with those of Jenner. Professor Munro Kerr pointed out that Smellie, who was born in Lanark in 1697, probably served his apprenticeship with either Gordon of Glasgow or Inglis of Lanark. He had been admitted a member of the Faculty of Physicians and Surgeons of Glasgow in 1733, and had received the M.D. degree from the University of Glasgow in 1745. He died four years after his return from London, but in these few years at Lanark he had written up the second volume of his cases and completed the third volume of his historical treatise. Tobias Smollett had edited the manuscript, but Smellie had passed away in 1763 before the work appeared in print. William Smellie and William Hunter stood out as the two most distinguished obstetricians this country had produced, but while Hunter had been a great scientist, Smellie's achievements had been those of the great obstetric surgeon. All through his writings one was impressed with his practical genius. Thanks to the aid of his friend Smollett, his writings were marked by a lucidity and terseness which was most impressive, cases being presented as clear-cut clinical pictures, which even now could be read with interest and profit. William Smellie's name would ever be held in honour.

New Dairy Research Institute

The Hannah Dairy Research Institute at Auchincruive, Ayr, was opened on April 25th by the Right Hon. William Adamson, Secretary of State for Scotland. At a luncheon which preceded the opening ceremony Dr. Walter Elliot, M.P., said that the institute was a new link in the chain of Scottish scientific institutions, and a new bond between the theoretical science of the universities and the practical science of farming. Thanks to the far-sighted spirit of Mr. J. M. Hannah, this Ayrshire institute would enable them to co-operate with the medical school of Glasgow, and to get into touch with the huge industrial population of the Clyde Valley, to whom problems of nutrition were becoming every day of more vital importance. The health of industrial communities depended upon the quality of the produce from agricultural areas, particularly milk. While fresh raw milk had valuable properties, certain things had to be excluded from it—for example, tubercle bacilli—whether the milk was boiled or unboiled. This institute formed part of a great administrative scheme, which also included the Rowett Institute at Aberdeen, and the Institute for Animal Genetics and the Plant Breeding Research Station at Edinburgh. He thought that this school of animal husbandry in Scotland was without a rival in the world. Sir Donald MacAlister, who presided at the luncheon, hoped that the co-operation referred to with the University of Glasgow, the Agricultural College, and other institutions of similar scope, would be maintained. In paying a tribute to those who had been responsible for the foundation of this institute, especially to Mr. Hannah, Sir Robert Greig mentioned that since the war donations by private persons and firms to research institutes in Scotland had amounted to £339,590. Mr. William Adamson, in declaring the institute open, said that, according to the last census of production taken in 1925, the milk and dairy produce of Scotland had risen from a total value of £4,500,000 in 1908 to £8,900,000. In 1925 the total number of cows in Scotland was 398,000, and the milk produced was estimated at 171,000,000 gallons. Of this, 137,000,000 gallons were used as liquid food, while

the remainder produced 52,200 cwt. of butter, 145,500 cwt. of cheese, and 102,000 gallons of cream. Of this total supply of milk, 59 per cent. came from the south-western counties of Scotland. The results of the recent large-scale experiment of supplying a ration of milk daily to school children had provided a striking illustration of the improvement in health, physique, and mental alertness resulting from the inclusion of a regular supply of pure milk in the diet of the growing child. Clean milk was an ideal human food, but it was important to remember that problems relating to the dairy cow had a direct bearing on the quality and hygiene of the milk supply. Mr. Adamson referred also to an experimental scheme devised to test the possibility of eradicating tuberculosis from dairy herds which was being put into operation by the institute. He considered that the value of research in this direction could not be overestimated.

Honour for Fifeshire Doctor

On April 29th Dr. A. L. S. Tuke was made an honorary freeman of the city of Dunfermline. Provost Gorrie, who presided at the ceremony, said that Dr. Tuke had practised among them for forty-four years, and during that period had taken a notable part in the life of the city of his adoption. Dr. Tuke possessed the qualities of devotion to duty, real understanding of human nature, unfailing patience, cheerfulness, and good temper, in addition to the technical skill which went to the making of a successful physician and surgeon. During the war it was said that no medical officer had displayed more energy and fought more successfully against bad sanitation and disease. Dr. Tuke had served as regimental medical officer of the Fife and Forfar Yeomanry, and of the Camel Corps, and as a divisional surgeon and D.A.D.M.S. From 1915 to 1919 he had served in the Egyptian and Palestine campaigns, and was awarded the Military Cross in 1916. In Dunfermline he had done pioneer work in organizing physical training among the youth of the city, and he had rendered signal services to the Dunfermline and West Fife Hospital in connexion with the recent successful appeal for £50,000 for extension purposes. In reply, Dr. Tuke referred to the changes in the conditions of medical practice that had taken place since he came as an assistant to Dunfermline in 1887. In those days, he said, the housing of the working classes consisted largely of but-and-ben and single-end houses, mostly overcrowded, in which the doctor had to face all kinds of illness, medical and surgical. Since then many improvements had been brought about, especially in dealing with cases of accidents in the mines. Thanks to the benefaction of his fellow burgess the late Mr. Andrew Carnegie, Dunfermline had been able to bring to a high standard many of the schemes required by legislation. He reminded his audience that Dunfermline had been the first town in Great Britain to introduce a complete system of school medical inspection, and to organize systematic physical training.

Glasgow Ear, Nose, and Throat Hospital

At the fifty-first annual general meeting of the Glasgow Ear, Nose, and Throat Hospital, held on April 22nd, Lord Provost Kelly, who presided, remarked that while Glasgow had a great variety of philanthropic institutions, none was more deserving of public support than the hospitals. The attendances at this hospital had risen in every department, and he was glad to observe that the subscriptions had also increased. Although the new building had been opened only some four years ago, it was already taxed to its utmost capacity, and the directors were considering plans for immediate extension. They proposed to proceed with the erection of a new block which would enable about 500 additional indoor patients to be treated annually. The necessary ground adjoining the hospital had been presented by an anonymous donor, and he supported the appeal of the directors for donations to meet the cost of the new building required. In reviewing the year's work he drew attention to the fact that 4,602 children under the age of 15 had been treated in the hospital during the year. Dr. R. Barclay Ness, consulting physician to the hospital, mentioned that the directors of the Glasgow and West of Scotland Radium Institute had granted a loan of radium to the hospital, which would enable its surgeons to deal much more effectively with malignant disease of the throat than had hitherto been possible.

England and Wales

Radium Treatment at University College Hospital

Dr. R. S. Pilcher, the Harker-Smith registrar of University College Hospital, London, has, in his annual report for 1930, made a valuable contribution to the treatment by radium of malignant and non-malignant conditions. A brief record of each case treated during the year is given, and a more complete analysis made of the results of treatment of menorrhagia and carcinoma of the cervix, the case lists of which have been discontinued. A few notes on the organization of the radium service show how thoroughly this has been carried out, ensuring that the exposure to radium is distributed over as many persons as possible. A whole-time physicist has been appointed by the hospital to work in conjunction with the radium registrar and radiologists. By a photographic examination he has shown that there is a marked difference between the specified and actual strength of the needles used. Periodic testing of the needles for leakage has shown many of them to be faulty. Dr. Pilcher states that a more efficient follow-up scheme has been instituted, which has secured the help of the Boy Scouts' Association in tracing living cases, those dead being traced by the courtesy of the Registrar-General through the General Register Office. Carcinoma of the lip, tongue, and mouth has been treated by interstitial irradiation with needles of low intensity combined with dissection of glands. In a case of carcinoma of the oesophagus at the level of the seventh dorsal vertebra the growth was exposed by a right side thoracotomy, and radium needles were stitched to the outer surface of the oesophagus and left there for nine days. Eight months after the operation the patient was very well, and was swallowing fluids and solids without difficulty. Inoperable cases of carcinoma of the rectum have not responded well to treatment, and in carcinoma of the breast radium is used only in inoperable cases, or in cases in which operation is contraindicated by age or by other disease. Two cases of carcinoma of the parotid complicated by facial palsy were treated by interstitial irradiation, with regression of the tumour and recovery from the facial palsy. The Stockholm technique has been adopted in the treatment of carcinoma of the cervix, and all cases are now exposed to a combination of radium and *x* rays. In the radium treatment of menorrhagia it has been found that better results have been obtained in essential menorrhagia than in menorrhagia due to fibroids, or to inflammatory and degenerative conditions. Other non-malignant conditions include dysmenorrhoea, benign skin lesions, ganglion of wrist, and otosclerosis. The following blood changes after radium treatment have been observed: in the red cells there is usually a fall in the total count, and occasionally a rise; in a few cases a high colour index has been found; in the absence of sepsis there is a fall in the total white count, the differential count showing a drop in the total small lymphocytes and

a rise in the mononuclears. Dr. Pilcher states that in past reports undue stress has been laid on vaginal changes following irradiation of the uterus, no case of vaginal stenosis having occurred in 1929 and 1930. It has, however, been a common sequel of cavitary irradiation of the vagina for carcinoma of the cervix. Two cases of blindness followed irradiation of sarcoma and carcinoma of the ethmoid region, in one of which blurring of the outline of the disc was found. Necrosis of bone has also complicated radium treatment. Deaths occurring during treatment were mainly due to secondary haemorrhage or broncho-pneumonia.

Midwifery Centre for Deptford

A midwifery centre organized by the Nursing Sisters of St. John the Divine was opened at St. John's Home, Deptford, on April 29th. The Nursing Sisters of St. John, a band of gentlewomen, were established in the middle of last century, as a "training institution for nurses, for hospitals, families, and the poor." In course of time district work was taken up in certain parts of London, including Deptford. Here, following upon the recent retirement of the sister-in-charge, Sister Constance, it has been decided to make certain changes whereby the Deptford home will be used entirely as a midwifery centre from which trained midwives will go out to attend and nurse patients in their own homes; in other cases they will act as maternity nurses for patients under the care of doctors. The reconstructed premises, which include provision for ante-natal and post-natal clinics, were opened by Dame Janet Campbell in the presence of a large company, including the mayors of Deptford and adjacent boroughs. The Bishop of Woolwich, who presided, said that the work done by the Nursing Sisters of St. John over many years would never be forgotten in Deptford; but conditions had changed, other societies of nurses had sprung up, and the special demand for maternity nursing had become more evident; the institution, therefore, had wholly adapted itself to that need, and eight midwives were already doing valuable work. Dame Janet Campbell said that several schemes had lately been put forward for a complete maternity service. Two fundamental points common to these schemes were, first, that every woman should have available for her confinement the services of a trained midwife and a doctor when necessary, and, secondly, that there should be supervision of the health of the mother from a date as early as possible in the pregnancy. At St. John's they were concerned chiefly with the part to be played by the midwives. Of late years the status of the maternity nurse had greatly improved, and it never stood so high in this country as at present. The fact that the midwife was recognized as an essential member of a team for maternity welfare indicated that she had won her place in lay opinion and in the opinion of her medical colleagues. The supervision of pregnancy was a relatively new conception. When the rules were first laid down by the Central Midwives Board, ante-natal care was not included, but now it was recognized that many risks could be avoided if the expectant mother were under skilled care before confinement. It was not fair to ask the midwife to accept medical responsibilities, and even when she was undertaking the confinement herself it was recommended that she should have associated with her a doctor, and that the patient should be examined once, twice, or three times during pregnancy. This recommendation had given rise to some misunderstanding as to the status and duties of the midwife, but there was no desire to interfere with her responsibility at the time of confinement in a normal case; the position was that she now had the advantage of calling in, if necessary, a doctor who was already familiar with the case and who knew what to expect. Dame Janet Campbell also spoke of the important social functions of the midwife in looking after the patient in her own home, in estimating her home conditions from the point of view of suitability for confinement, and in encouraging her to go regularly to the ante-natal clinic. In the matter of clinics, she said, this country was far in advance of France and Germany; the progress which had been made was amply illustrated by this well-equipped centre at Deptford, where a group of competent midwives worked under a head with a great amount of experience. She commended the centre, which also acted as a teaching school, to the local authorities and practitioners.

Incidence of Venereal Disease in London

The new cases of venereal disease seen at the clinics in London in 1930 numbered 16,707, an increase of 722 on the previous year. In addition, 10,162 persons presented themselves for examination, but were found not to have venereal disease. The total attendances of patients were 836,219, compared with 768,872 in 1929, and smaller numbers in each of the three preceding years. Of the total number of new cases in 1930, those of syphilis reached 5,225, those of gonorrhoea 11,123, and those of soft chancres 359. Provision is made at the various hospitals for in-patient treatment, and the number of days of treatment of in-patients in 1930 was 21,033 in the case of males, and 30,183 in the case of females; the corresponding figures for 1929 were 23,123 and 28,399 respectively. At the request of medical practitioners, 33,309 bacteriological specimens were examined free of charge at the hospitals. The expenditure of the London County Council on arrangements for diagnosis and treatment for 1931–32 is estimated at £95,995; adjacent authorities share in this to the extent of 17 per cent. In the hospitals transferred to the Council from the boards of guardians it is proposed to concentrate venereal disease cases in six units, provided with modern equipment, where treatment can be supervised by specialists and the work linked up as far as possible with the clinics. The general hospitals chosen for the establishment of the centres are Bethnal Green, Fulham, Lambeth, St. Charles', St. Peter's, and St. Stephen's, at which total accommodation can be provided for 122 male patients, 89 female patients, and 8 children.

Coroners' Inquests in London

The number of deaths reported to London coroners in 1930 was 8,037, of which 2,591 took place in mental hospitals and other institutions. Inquests were held in 3,877 cases, a decrease of 464 on the number for the previous year. Of the inquests, 213 were held on infants under 1 year of age. The coroners directed, or requested, post-mortem examinations in 3,005 of the inquest cases, and in 2,237 of the remaining cases, in which no public inquiry was necessary. A verdict of murder was returned in 11 cases, and of manslaughter in 5. The total number of suicides was 594, a decrease of 42 on the year. Deaths from want of attention at birth decreased from 36 to 34, and deaths from accident from 2,196 to 2,073. There were 60 deaths by drowning. A verdict of "death from natural causes" was returned in 854 cases, and of "cause of death unknown" in 9. Inquests on newly born children decreased from 74 to 54, and verdicts of murder of newly born children were returned in 6 cases. In 27 cases it was decided that the child was stillborn. Excessive drinking accounted for 66 deaths, an increase of 1. The total cost to the London County Council of inquiries made by coroners and of inquests, including standing charges for coroners' salaries and the rent of coroners courts, was £37,552. Of the inquests, 1,221 were held with juries.

Correspondence

FRACTURES OF THE LONG BONES

SIR,—In your issue of May 2nd there appears an extremely interesting article by Mr. C. H. Fagge on the treatment of simple fractures of the long bones. So many points of discussion are set forth that I think a few remarks may profitably be made on the problems he has brought forward, or at least on some of the methods he advocates to overcome these difficulties.

In the discussion on supracondylar, or transcondylar, fracture of the humerus, Mr. Fagge has, I feel sure, quite unwittingly fallen into a very grave error—namely, that of misrepresenting the writings and teaching of another surgeon. He is describing the method adopted and taught by Sir Robert Jones, and, after quoting small isolated portions of one of Sir Robert's most recent articles, he then continues: "I assert without fear of contradiction that posture cannot be relied upon to reduce deformity (and I feel sure from the context that Sir Robert Jones has insisted on this for years)." I have also read this article, and every other article on this subject which Sir Robert Jones has published, and I can find not one atom of evidence to support the contention that he has ever suggested that position can reduce the deformity of a supracondylar fracture. In every one of these articles the instructions in regard to the reduction of the fracture, both in the script and by a series of diagrams, is so explicit that I cannot find the slightest reason for any medical man being unable to carry them out efficiently and easily.

The next point brought up by Mr. Fagge is in connexion with the occurrence of what is known as Volkmann's ischaemic paralysis, and the implication here is that the position of flexion is at least one great factor in the causation of this condition. In my experience the occurrence of the ischaemic paralysis is by no means so frequent as it was twenty years ago, when the treatment of these fractures was almost universally carried out with the elbow at right angles. The reason for this decided and desirable improvement seems to me to be due to the better teaching which doctors and students have had in the handling of these fractures during the past two decades. The usual teaching that Volkmann's ischaemia is always the doctor's mistake, and is due to too tight splinting or bandaging, is certainly incorrect, for I have seen two cases here of sailors who had sustained a supracondylar fracture of the humerus whilst at sea, and who have never had a splint or bandage applied. Yet, by the time they arrived in port the ischaemic contracture was advanced in both cases, and required treatment.

Mr. Fagge surely does not give us his views very clearly as regards retention of a supracondylar fracture when he insists so definitely that retention after reduction is unnecessary. This desirable state of affairs might be possible if all these fractures were like the displaced epiphysis which Mr. Fagge demonstrated during operation to his Firm, but unfortunately in the great majority of cases the line of fracture is not transverse, but passes obliquely from in front upwards and backwards. Therefore the tendency is, and must be, for a redisplacement of the fracture, especially when we take into consideration the muscular pull, which is by no means negligible, and the leverage of the forearm in whatever splint the right-angled fixation is maintained.

Finally, I may say that, having treated many hundreds of these fractures myself, and in my hospital clinics, in the position of flexion after reduction as advocated by Sir Robert Jones, I am able to state that ischaemic contracture has not occurred in any of them.—I am, etc.,

Liverpool, May 4th. T. P. MCMURRAY.

BLOOD PRESSURE AND LIFE ASSURANCE

SIR,—The question raised by your correspondent last week can be answered by reference to records of blood pressure readings such as I have regularly kept for the last twelve years.

These records show, among other points: (1) the range of oscillation of the needle of the tycos aneroid for each 10 mm. of Hg pressure from its start to its cessation; (2) with regard to auscultation they show (*a*) the lowest point at which any sound is audible, (*b*) the point when the first loud sound is audible, (*c*) the range through which the maximal sound is audible.

A study of such records shows that if the term "diastolic pressure" refers to the blood pressure during diastole the level of that pressure is more accurately indicated by the lowest point at which any sound is heard than it would be by the point where a better defined sound was audible. There is a close correspondence between the point at which definite oscillation of the tycos needle commences and the lowest point at which a sound is audible.—I am, etc.,

Birmingham, April 28th. T. STACEY WILSON.

SIR,—I think that Dr. Maurice Shaw is to be congratulated on his courage in pointing out in to-day's issue of the *Journal* that there are a large number of medical men who do not understand the correct method of estimating the diastolic pressure. Whether it is a wise thing to ask them to measure something that has no existence is, however, quite another matter. Personally, I do not think the majority of medical men and students can be blamed for their incapacity, because they have been so badly taught. Is there a teacher in a good medical school who is able to demonstrate the connexion between any of the sounds heard over the brachial artery with that which is known as the diastolic blood pressure?

In my article which appeared in the *Journal* of February 8th, 1930 (p. 242), I described a way of estimating the basic pressure in the brachial artery by means of two sphygomanometers, one above the other on the same arm. The method is purely objective, and is not dependent upon hearing any sounds, while it offers no technical difficulties to any medical man. It has the additional advantage of emphasizing the fact that the basic pressure varies for all the arteries, a point of some importance if we wish to form a fairly good conception of the disorder from which a patient may be suffering.

I think it is time for the members of the profession to have a satisfactory explanation of the causation of the sounds heard over the brachial artery as well as of those heard over the heart, because, if we do not know the causation of the normal sounds, how can we draw any reasonable conclusions from the modifications of those sounds which occur during disease? You have given me opportunities on many occasions to draw attention to this impossible state of our ignorance, but I trust now that Dr. Shaw has made reference to the incapacity of so many medical men, some steps will be taken to solve the problem.—I am, etc.,

Swansea, May 2nd. G. ARBOUR STEPHENS.

ACUTE URETHRITIS IN MUMPS

SIR,—I was interested in the letter of Dr. Arthur Spence on this subject. On page 91 of my book *Common Diseases of the Male Urethra*, published in 1917, I described a case of profuse urethritis during mumps. On several occasions since I have been called into consultation over similar cases. The practitioners have usually

expressed surprise when I have pointed out that profuse urethritis can occur during mumps when complicated by swelling of the testicles. It seems to me important that this combination of events should be more fully recognized, otherwise a patient can easily be accused unjustly of venereal infection when all the time he is merely suffering from mumps.

I should like to take this opportunity of pointing out that swellings of the testicles may occur as long as eight to ten weeks after the primary attack of mumps, and it is sometimes hard to persuade practitioners that such swellings are not due to tuberculosis, but are late complications which will subside naturally in the course of a few weeks. The swelling of the testicles met with in mumps can be readily recognized by those accustomed to see such cases, but is difficult to describe in words. There is a curious diffuseness about the swelling, accompanied by a feeling as of fluid effused into the surrounding tissues, resembling very closely the feeling of the enlarged parotids or enlarged salivary glands met with in this disease.

Another observed fact not widely known is that at the onset of subacute tuberculous epididymitis a mild urethral discharge may appear and persist for some weeks. This discharge contains pus cells, but is sterile, and as yet I have not been able to demonstrate tubercle bacilli in it.—I am, etc.,

London, W 1, May 4th. FRANK KIDD.

SCHISTOSOME WORMS AND SCHISTOSOME MONSTERS

SIR,—Probably few medical zoologists are aware that the term "schistosome," so commonly used nowadays as a synonym of the bilharzia worm, has also been used for nearly a century by teratologists for a fairly common type of monstrosity in domesticated animals.

In 1832 Gurlt devoted the second volume of his *Lehrbuch der pathologischen Anatomie der Haus-Säugethiere* to an account of the various types of monsters, and classified them ingeniously in genera and species, following the methods of zoological nomenclature. His third Order, containing forms "Fissio corporis abnormis," comprised four genera, including the "genus" *Schistosomus*, with the three species *Schistosomus reflexus*, *Schistosomus contortus*, and *Schistosomus microchirus*.

In 1908 Eisenbarth described "Ein Fall von *Schistosoma reflexum*" (*Wochenschrift für Tierh. Viehzucht*), and in 1927 Notter recorded a series of nearly 200 cases in sheep, cattle, goats, horses, dogs, and cats in a paper entitled "Schistosomen beim Schwein" in *Virchow's Arch. f path. Anat.*

It is somewhat amusing to find that these two papers are listed by Dr. M. Khalil in the *Bibliography of Schistosomiasis* recently published by the Faculty of Medicine of the Egyptian University. In the citation of Notter's paper the original title is replaced by the translation "Schistosomiasis in pigs"!

These references have not appeared heretofore in helminthological bibliographies, but, as they may now make their way into medical and veterinary textbooks, owing to the obvious importance which attaches to an apparently overlooked species, and to a disease in an important domesticated animal, I think that I should draw attention at once to these curiosities of medical bibliography instead of awaiting their correction in the future edition which the compiler promises.

Perhaps I should take this opportunity also of warning medical bibliographers to avoid listing a paper entitled "Variation des parasites atmosphériques pendant l'eclipse de lune du 2 avril, 1931," which has just appeared in *Comptes Rendus de l'Académie des Sciences*.—I am, etc.,

London School of Hygiene and Tropical Medicine, May 5th. R. T. LEIPER.

NON-LUETIC ARGYLL ROBERTSON PUPILS

SIR,—In the *Transactions of the Ophthalmological Society*, 1924 (p. 38), I reported seven cases of abnormal pupil reaction under the above title. At the congress which is just completed I added eight to this number.

The features of the pupils are that they are quite inactive to light stimulus, with convergence they contract in a characteristically slow manner and relax as slowly, are more common in women than in men, are most often unilateral, and, above all, are not related to syphilis.

I have to-day seen a medical man, aged 70, in perfect health in every way, who has this type of pupil. To his knowledge he has had it for thirty-five years, and the point of especial interest is that he states that his sister and a granddaughter each have a similar condition.

I have not previously come across a case showing a hereditary tendency.—I am, etc.,

London, W.1, May 1st. R. FOSTER MOORE.

CONCENTRATED ANTIPNEUMOCOCCAL SERUM IN THE TREATMENT OF LOBAR PNEUMONIA

SIR,—In the *British Medical Journal* of April 25th (p. 701) there appeared under this title an article on which we should like to offer some comments.

The conclusions as to the beneficial effect of the serum in this particular case seem to be based on: (1) the fact that a considerable degree of consolidation of the left lung, as diagnosed by clinical and radiological examination, became almost completely resolved during the last eighteen hours of life; (2) the improvement in the patient's general condition subsequent to the commencement of serum therapy; and (3) the determination of free antipneumococcal antibodies in the blood serum, post mortem, ten hours after the last administration of antipneumococcal serum.

Argument in a complicated and unusual case such as this is very difficult; and on this ground alone we consider it unsuitable for illustrating—as the authors claim—"the response which is to be anticipated from serum treatment of lobar pneumonia." In addition, grave doubt can be cast on the justification of their claim.

In the first place, the fact that there was such very extensive fibrinous pleurisy (diagnosed clinically and confirmed at post-mortem) must have made the recognition of the extent of consolidation in the subjacent lung very difficult, and therefore the rate and degree of resolution hard to estimate. Secondly, in regard to the clinical improvement, significance cannot be entirely denied the fact that the patient died ten hours after the time when an injection of serum was last considered necessary. To regard death as due to an unavoidable accident, and not contributed to in any way by the pneumococcal infection, seems to us to be making a large assumption, and to deduce "severe disturbance of the autonomic nervous system" from the existence, in the course of a febrile illness, of a tachycardia uncontrolled by digitaline, equally unjustifiable. Lastly, the demonstration of free antibodies in the blood serum at death loses its force unless the writers can prove that, although the primary infective process had been overcome (to accept their own opinion without further examination), death was not contributed to by processes, set in train by the pneumococcal infection, which the serum was unable to influence.

We contend that this case is of such a complicated and unusual nature that it is impossible to correlate the clinical course with the effects of therapy in any decisive way. We suggest that it is, in any event, unjustifiable from a single case to draw conclusions as to the general question of the effect of concentrated antipneumococcal serum in a disease so notoriously uncertain in its course as lobar pneumonia. There need be no hesitation in saying that it is only the results of large series of cases treated with serum, and contrasted with equal numbers of controls, that can reveal what the value of these preparations is. Until such investigations have been made with regard to the particular serum here employed, the reporting of single cases is apt to be misleading.—We are, etc.,

J. M. ALSTON, M.B., M.R.C.P.Ed.
J. G. MCCRIE, M.B., M.R.C.P.Ed.

Edinburgh, April 27th.

SIR,—Having read with the greatest interest the amazing case published under the above title (*Journal*, April 25th, p. 701), and the no less amazing conclusion drawn by the authors, that it affords "unassailable evidence in favour of the use of concentrated antipneumococcal serum early in pneumonia," I should like, in the interests of scientific investigation, to voice some very obvious criticisms of the diagnosis, treatment, and conclusions. Had the case been published merely as an interesting example of the possibilities of being misled by physical signs and symptoms no criticism would be justified, but since it is used as a special plea for the general employment of a very doubtful and possibly a dangerous form of treatment in pneumonia it cannot be allowed to pass unchallenged.

The case presented none of the features of pneumonia on admission, but it did present all the signs and symptoms of a subdiaphragmatic retroperitoneal inflammatory effusion, with, later, extension of infection to the left pleura via the left cupola of the diaphragm, producing the serofibrinous pleurisy found post mortem, which was mistaken during life for a massive consolidation of the lung. The left lung (in which there was no pneumonia) would collapse as soon as the pleural cavity was opened via the diaphragm at the necropsy, and the so-called products of rapid resolution found in it (and attributed to the efficacy of the serum) were the result of aspiration of sputum derived during life from the undoubtedly early pneumonic process in the right lung. A patient with a pneumonia in the right lung during the week following an upper abdominal operation would be certain to aspirate some of the pneumonic sputum into the left lung. Indeed, this mode of extension, owing to the extreme difficulty of expectoration, is one of the anxieties of the physician in attendance. The danger is increased when the left pleural cavity is infected to the extent shown at the necropsy in this case. The right lung pneumonia did not start until twenty-four hours after admission, and showed, at the post-mortem examination, congestive features not inconsistent with a third- or fourth-day pneumonia in such a patient. This pneumonia was only an incident in the grave disease for which the patient was admitted, and which was due to some other insidious general infection, possibly one of the expressions of the prevalent "gastric influenza."

The signs of an inflammatory retroperitoneal effusion are: the Hippocratic state of the patient on admission with grave collapse, the temperature of 97° F., the signs of an upper abdominal catastrophe very suggestive of acute haemorrhagic pancreatitis, the persistent tachycardia, pulse 160 for three days uninfluenced by digitaline (after the patient had recovered from the initial peritoneal shock); this tachycardia was due to pressure of the effusion on the coeliac ganglia. The sympathetic irritation conduced, no doubt, to the gastric dilatation from which the patient died.

This is admittedly a stormy case, in which the patient could not be frequently disturbed for examination; but it gives the impression that too much reliance was placed on the *x*-ray examination and too little on the natural phenomena of the disease as expressed in the patient, since a very massive fibrinous pleurisy was diagnosed during life as consolidated lung. Whether or not the serum benefited or prejudiced the patient it is impossible to say, but there are no grounds, on the evidence submitted, for claiming that this remarkable case affords "unassailable evidence in favour of the use of concentrated antipneumococcal serum." The authors' use of the word "unassailable" permits me to request you to publish this letter in the interests of scientific justice.—I am, etc.,

Bradford, April 27th. A. HAYES SMITH.

POST-INFLUENZAL COUGH

SIR,—Observations and contributions on the etiology and treatment of persistent cough following influenza are important. It is my experience that in some cases the irritation of the pharynx or lower respiratory tract is secondary to a persistent nasal infection. It may often be sufficient to treat the tracheitis or pharyngitis and to allow the nasal infection to clear up spontaneously. In cases where the cough persists in spite of this treatment, attention should be directed towards the nose, and the possibility of an antral or other nasal sinus infection should not be overlooked.—I am, etc.,

Birmingham, May 4th. F. DOUGLAS MARSH.

THE MODERN CONCEPTION OF EARLY PHTHISIS

SIR,—Although I admit the enterprise and courage of Dr. H. V. Morlock in his eager attempt to present to the general practitioners of Bermondsey an outline of the work of Redeker (not Redecher) upon the early stages of phthisis, both in children and in adults, I doubt his wisdom. This subject teems with difficulties, and it is not wise at one swoop to discredit the observations and conclusions of Fachmänner, who have devoted their lives to the careful macroscopical and microscopical examinations, not only of "the end-results seen at necropsy," but also of all the stages of phthisis from the beginning to the end. Even to-day the anatomists Hübschmann, Beitzke, Löschcke, Baden, Hart, and the pioneer radiologists Gräaf and Küpferle, who controlled their observations with post-mortem comparisons, do not agree with Redeker's views upon the early origin of all forms of phthisis.

We dare not trust implicitly to *x*-ray shadows in laying the foundation of a new theory. X rays in a sense work objectively, but the objects are shadows, and the interpretation of shadows has a large subjective bias. Certainly *x*-ray shadows should never displace pathological anatomy or a thorough physical examination. As an aid in diagnosis *x*-ray pictures are invaluable. One may even criticize Dr. Morlock's somewhat aggressive statements out of Redeker's own mouth. Redeker writes in 1930:

"We believe that what is called 'early infiltrate' represents no patho-morpho-logical-genetic entity. We know merely that it consists of 'Neuherd-bildungen' that appear with the signs of perifocal inflammatory infiltration, show a great tendency to central caseation and softening, often spread more or less rapidly, and thus lead very often to the development of an acute or chronic phthisis. Whence the bacillus, that causes the lesion, comes is still undecided."

This perifocal inflammation is akin to Koch's phenomenon, and therefore familiar to those who have constantly studied the effects of tuberculin *in vivo*. It is

the allergic manifestation of the central focus, which owes its origin to what Redeker calls "superinfection" by the air passages, because 65 to 70 per cent. of these cases occur in homes where open phthisis exists. Therefore early infiltrates occur in families in which open phthisis exists. But there are many cases of phthisis that cannot be traced directly to this exogenous origin: Birch-Hirschfeld's beautiful demonstration in 1899 at the Tuberculosis Congress in Berlin helps us to realize another form of early phthisis. The work of Anders and Schmoe of Freiburg upon the relation of infection of the subpleural glands to phthisis is another "tree in the wood." Clinical histories tell us that phthisis may occur without superinfection, and clinical examination will sometimes prove that phthisis may begin in the upper part of the lungs, even in the axillary area, as we have long known. Before Redeker appeared as a new prophet, I had learned to disregard the tip of the lung, and concentrated, according to the teaching of Birch-Hirschfeld, on the suprascapular fossa and surrounding area exposed by making the patient fold his arms. The general practitioner should follow this practice.

Curiously, Dr. Morlock does not once mention tuberculin, which is more useful than *x* rays, in early diagnosis, although Redeker's work shows that he gives pride of place to tuberculin in the diagnosis of early cases of phthisis. If Dr. Morlock would come to my clinic at 11, Nottingham Place, I would arrange to put before him the charts of several cases of early infiltrate, some with cavitation and softening, in which large doses of tuberculin have yielded highly satisfactory results without any resort to artificial pneumothorax. The tubercle bacilli, if present, have disappeared, the physical signs are those of a healing or healed lesion, and the patients are able to work. Three of the patients were under the care of three physicians at Brompton Hospital, and one of them escaped artificial pneumothorax without any detriment. So far I have not resorted to artificial pneumothorax because tuberculin yields very satisfactory results.

Accordingly, I would warn general practitioners not to accept the teaching that *x*-ray examinations are the "be-all and end-all" either in diagnosis or in treatment. In every case of phthisis, actual or threatening, the order of examination should be, as even Redeker teaches: (1) examination of patient and of his personal and family history, including a thorough physical examination, which I fear is not always easy to make; (2) examination of the phlegm, and, if no tubercle bacilli can be found, testing with tuberculin; and (3) examination by *x* rays. —I am, etc.,

W. CAMAC WILKINSON, M.D.; F.R.C.P.

London, W., April 30th.

PULMONARY ARTERIO-SCLEROSIS AND AYERZA'S DISEASE

SIR,—I have been interested to read the paper on pulmonary arterio-sclerosis, by Drs. C. G. Paine and Robert Platt, in the *Journal* of April 25th (p. 698). I cannot but feel that the effect of their statements may serve to add still further to the confusion that already exists on the subject of Ayerza's disease and pulmonary arterio-sclerosis.

Arrillaga in 1913, referring to the syndrome of "cardiacos negros," as manifested by dyspnoea, polycythaemia, cyanosis, clubbing of the fingers, recurrent haemoptysis, cough, vertigo, and somnolence, pointed to the etiological factors as all disturbances leading to pulmonary emphysema. Dr. F. Parkes Weber, in the *Journal* of October 30th, 1920 (p. 658), drew attention to the fact that the subjects most commonly presenting the features of this syndrome were patients suffering from long-standing asthma.

The paper by Drs. Paine and Platt assumes at the beginning that, whether there is a pre-existing disease of the lungs or not, the onset of arterio-sclerosis of the pulmonary arteries will alter the course of the disease, and produce a recognizable clinical picture of its own. I submit that this assumption involves confusion of cause and effect. Professor H. M. Turnbull, in an admirable paper on alterations in arterial structure and their relation to syphilis (*Quarterly Journal of Medicine*, 1915), has drawn attention to the fact that obstruction in the lesser circulation will lead to local hypertension, and this will cause right heart hypertrophy, with varying intimal hypertrophy and degeneration of the pulmonary arteries.

Omitting the rare cases of syphilitic arteritis of the pulmonary artery, congenital abnormalities, and the more acute cases of pulmonary embolism and thrombosis, the rest of the cases showing obstruction in the lesser circulation will fall into that well-known group of chronic cardio-pulmonary diseases especially illustrated by mitral stenosis, fibrosis of lung from various causes, and emphysema. These patients gradually develop the features of Ayerza's syndrome, and if they avoid dying of intercurrent infections the effects of congestive heart failure may be superadded. The whole of the signs and symptoms are adequately explained as the results of venous and capillary obstruction in the lesser circulation. Arterio-sclerosis of the pulmonary arteries is merely secondary, and not likely to add much to the obstruction already existing. Hypothetically, any effect that might be produced by arterio-sclerosis of the pulmonary artery would be merely mechanical—that is, an addition to the hypertension in the lesser circulation. It would be ridiculous to suggest that in chronic cardio-pulmonary diseases, where hypertension already exists, the results of such an addition would "alter the entire course of the disease and produce a recognizable clinical picture of their own."

The three cases described by Drs. Paine and Platt illustrate the ordinary features of venous and capillary obstruction in the lesser circulation, with added congestive heart failure.

Patient, aged 52 years, had bronchitis for many years with emphysema. She showed dyspnoea and cyanosis, and died with ascites and generalized oedema. No blood Wassermann test was performed, either ante or post mortem.

Patient, aged 63, had "winter bronchitis" for a few years, and died with cyanosis, oedema, ascites, and enlarged liver. Post-mortem examination showed severe generalized atheroma, but no mention is made of the condition of the coronary arteries. No blood Wassermann test was performed, either ante or post mortem.

Patient, aged 46, had bronchitis for thirty years. She showed dyspnoea and cyanosis, and died with oedema, ascites, and enlarged liver. Clinical examination showed that movements of the chest were symmetrical, but very restricted. Air entry was poor, and percussion note resonant throughout. In spite of this it is stated that there was no pronounced emphysema. The Wassermann reaction was negative.

It is difficult to agree with Drs. Paine and Platt that the cases described were "of some rarity."—I am, etc.,

London, E.1, April 26th. M. TREE.

TREATMENT OF MALIGNANT GROWTHS WITH EXTRACTS OF PARATHYROID GLANDS

SIR,—Extracts of parathyroid glands, freed from the blood-calcium-raising factor (Collip) by precipitation, have been found to inhibit growth in young animals and in Jensen rat sarcomata.[1] A growth-inhibiting factor has been demonstrated, but has not yet been isolated.

Extracts of parathyroid glands thus prepared have been injected intramuscularly into human subjects suffering

[1] *Proc. Physiol. Soc.*, October, 1930, lxx.

from various types of carcinomata and sarcomata, including spheroidal-celled carcinoma, columnar-celled carcinoma, endothelioma, sarcoma, and glioma. The cases have been treated at the Soho Hospital for Women, the Westminster Hospital, and St. Bartholomew's Hospital. Some improvement has been noted, and the results are sufficiently encouraging to warrant a continuation of the investigation. It is as yet too early, and the cases are too few, to make a detailed statement.

In carrying out this investigation I have been, and am, greatly indebted to the generosity of the firm of Messrs. Allen and Hanburys Ltd. for supplying the extracts used. —I am, etc.,

J. H. THOMPSON, B.Sc.,
Melchett Research Scholar, Royal College of Surgeons; Lecturer in Physiology, University of London, King's College.

Royal College of Surgeons of England, April 24th.

THE CANFIELD OPERATION

SIR,—I quite expected Sir James Dundas-Grant to ask whether I had ever performed the Canfield operation. I am conversant with the technique of the operation, but I have never done it, because I consider it wrong in principle. During the last fourteen years I have performed over 2,000 operations on the nasal sinuses, and in nearly every case the antrum was opened. The Canfield is an intranasal operation; the Denker is done through the mouth. In both the objective is similar—namely, to attack the "fo'c's'le" as Sir James terms the anterior angle of the antrum. I have given the Denker a good trial, but prefer the Caldwell-Luc, without interfering with the inferior turbinal. Last year, apart from tonsil and adenoid operations, I performed some 450 operations. Of these 80 were on the nasal sinuses. Among the whole number, private and hospital, over 2,000, I have had three deaths, two following operations on the ethmoid, and one following operation on the frontal sinus. I am sure Sir James Dundas-Grant will admit that my experience warrants an opinion on this subject.—I am, etc.,

Maidstone, April 27th. J. ALDINGTON GIBB.

EPIDEMIOLOGY OF VENEREAL DISEASES

SIR,—In my remarks in the discussion on Colonel L. W. Harrison's paper on this subject (*Journal*, May 2nd, p. 752), the number of cases admitted as suffering from acute notifiable infectious diseases, and in which the final diagnosis was syphilis, ranging from 2 in 1914 to 15 in 1912 during the period 1909–14, and from 0 in 1923 to 7 in 1928 during the period 1923–29, applies to the admissions to all the fever hospitals of the Metropolitan Asylums Board, and not to a single hospital as stated in your report.—I am, etc.,

London, S.W.6, May 2nd. J. D. ROLLESTON.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on April 30th the following medical degrees were conferred:

D.M.—R. M. J. Harper, W. H. Bradley.

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated.

ACADEMIC DIPLOMA IN PUBLIC HEALTH.—R. J. Muzumdar. *Part I:* R. E. Barrett, E. Cochrane, May P. Cowell, H. A. Crouch, N. J. England, D. W. G. Faris, Marguerite M. Fenn, H. S. Gear, J. E. Howard, I. J. Jones, G. C. Kelly, H. Machado, Hilta I. C. Pfister, J. Portelly, L. E. J. Poulier, Dorothy M. Rees, Florence M. Rhodes, J. T. N. Roe, A. P. Ross, B. M. Roy, A. T. Till, W. J. Webster, H. B. Wilson.

UNIVERSITY OF GLASGOW

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—W. F. Bagot, J. S. Carslaw, L. F. Chan, J. A. Cook, A. Dalinsky, D. C. Dobson, M. Donnelly, R. M. Dunstone, W. B. C. Gibson, K. J. Grant, J. Guyer, A. Hair, T. C. Houston, J. H. Jeffrey, A. S. M'Farlane, D. M. Mackenzie, I. M. MacLennan, J. E. Redmond, A. H. B. Rhodes, J. Rosen, K. Sagoe, C. J. Scott, J. T. Simpson, J. I. Snodgrass, T. D. Thorne, J. A. Tierney, J. E. Walcott, G. A. Weir, T. M. Wilson, W. H. M. Wilson, W. Wolfson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A quarterly meeting of the Royal College of Physicians was held on Thursday, April 30th, when the President, Lord Dawson of Penn, was in the chair.

Fellowship

The following were elected Fellows of the College:

Hablitstein David Haldin-Davis, M.D.Oxf., Gustave Jean Philippe Monod, M.D.Paris, John Rupert Collins, M.D.Dublin, Alexander Greig Anderson, M.D.Aberd., Gilbert Innes Strachan, M.D.Glas., Hugh James Orr-Ewing, M.C., M.D.Lond., George Robinson Pirie, M.B.Toronto, Thomas Forrest Cotton, M.D.McGill, Hugh Stannus Stannus, M.D.Lond., Thomas Herbert Oliver, M.D.Manch., Frederick John Nattrass, M.D.Durh., Alfred Alexander Webster Petrie, M.D.Lond., Norman Brandon Capon, M.D.Liverp., Reginald Hilton, M.D.Camb., Adam Patrick, M.D.Glas., Sir Bernard Spilsbury, M.D.Oxf., Walter Russell Brain, M.D.Oxf., Davis Evan Bedford, M.D.Lond., John Forest Smith, John Davy Rolleston, M.D.Oxf., Edgar Hartley Kettle, M.D.Lond., Leslie John Witts, M.D.Manch., James Andrew Gunn, M.D.Ed.

Membership

The following candidates, having satisfied the Censors' Board, were elected Members of the College:

Melville Huia Aiken, M.B. New Zealand, Mohammed Ali Arafa, M.B.Cairo, Eric Tom Bates, *M.B.Liverp.*, Frank Howard Beare, M.D.Adelaide, Wilfred Venn Bowman, L.R.C.P., Edward Francis Brooks, *M.D.Toronto*, Thomas Benjamin Davie, M.D.Liverp., Thomas Amwyl Davies, M.D.Lond., Claude Ernest Dolman, M.B.Lond., Archibald Gilpin, M.B.Lond., John Mahse Graham, M.B.Camb., Cecil John Hackett, M.B.Adelaide, Donald Frederick Kanaar, M.B.Lond., Walter Montague Levitt, M.B.N.U.I., Chisholm McDowell, M.B. New Zealand, Eric Gordon Oastler, M.B.Glas., Catherine Jane Ormerod, L.R.C.P., David Preisked, M.B.Lond., Seenivappah Ramanathan, L.R.C.P., William Gordon Sears, M.D.Lond., Athelstan da Costa Stoute, L.R.C.P., Oliver Frank Thomas, L.R.C.P., Alexander Clive Rees Walton, M.B.Birm., Theodore Henry Whittington, M.D.Lond., Ernest Alan Wood, M.B.Lond., Dorothy Evelyn Wright, M.D.Lond.

Appointment of Representative

The President (Lord Dawson of Penn) was appointed representative of the College on the Governing Body of the British Post-Graduate Hospital and Medical School; also representative of the College to the forthcoming centenary celebrations of the Harveian Society of London.

Licences

Diplomas of L.R.C.P. were conferred upon the following 106 candidates (including 11 women) who have passed the requisite examinations and have complied with the by-laws:

R. C. Abel, H. Allan, P. R. Allison, *Inez E. Banner, S. Barigrasser, J. S. Barker, A. J. W. Beard, N. J. Bee, D. R. Bharucha, N. Bissada, *H. Bloom*, A. D. Bourne, S. A. Bower, G. D. S. Briggs, W. A. C. K. N. Bruce, H. G. H. Butcher, G. N. Carrell, *P. H. Charlton*, C. N. Chitnis, H. L. Chave, I. G. I. Culank, H. L. N. Davies, J. O. F. Davies, E. C. Dayus, Yolande M. de la Pasture, J. Dobson, *W. Dodd, G. A. Emmerson, D. Erskine, L. P. J. Evans, S. H. Ferguson, B. Fine, J. Finer, Lena Finkelstein, A. C. Fraser, J. W. O. Freeth, L. T. Furnivall, K. H. Gaskell, S. E. Godwin, I. Gold, I. T. Griffiths, Constance A. Grove, E. A. Gudgeon, K. Harris, K. Hazell, C. B. Hinkley, G. Hyman, F. J. V. Jaensch, S. S. Jaikaran, I. O. Jones, A. Kahan, G. D. Kersley, *D. H. Klugman*, L. E. D. Knights, J. S. Knox, Nancy Laughton, C. H. Levick, D. L. Lewis, A. Liberis, J. W. S. H. Lindahl, A. B. MacEwan, R. W. McNabb, J. M. Matthew, R. H. Moore, I. More, G. G. Mowat, *D. H. Murphy*, W. H. Mylechreest, W. McN. Niblock, J. E. A. O'Connell, Elizabeth S. G. Owen, R. Palmer, W. R. Parkes, R. McI. Paton, H. A. Phillips, D. R. Prem, W. M. Priest, R. V. C. Richards, H. J. Riley, S. Rosenbloom, A. G. Sanders, E. M. Sastry, Ida B. Saxby, J. Scholefield, P. G. Scott, A. Segil, J. H. Shakespeare, D. A. Smith, R. B. Fitz A. U. Somers, K. S. Southam, T. C. Stamp, H. W. G. Staunton, A. B. Stokes, N. S. Taggart, H. S. Tibbits, Marion E. Townsend, D. S. Valentine, E. D. Ward, *Evelyn A. M. White, Margaret M. White, G. A. W. Whitfield, R. G. Wilbond, J. L. Wild, I. G. Williams, Mary Wills, C. Wilson.

* M.R.C.S. previously granted.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A meeting of the council of the College was held in Glasgow on April 21st, with the president, Professor W. Blair Bell, in the chair. The following Members of the College were admitted to the Fellowship: Ernest Farquhar Murray, William Henry Francis Oxley, and Gilbert Innes Strachan. The following signed the Oath, and were admitted to the Membership of the College: Gerald Fitzmaurice Keatinge, Percy Malpas, Edward Lawton Moss, and Frank Neon Reynolds.

The second annual general meeting of the College was held in the Lister Memorial Hall, Glasgow, on April 22nd, with the president in the chair. There was a large attendance of Fellows and Members.

The honorary secretary reported that the vacancies on the council, created by the statutory retirement of one-third of the members thereof, had been filled as follows: Fellows—Henry Russell Andrews, Herbert Leith Murray, Bethel Solomons, and Harold Beckwith Whitehouse, all of whom had been renominated without opposition and re-elected. John Eric Stacey was elected by vote as a representative of the provincial members.

The adoption of the report of the council and of the financial report and balance sheet, all of which had been circulated, was proposed by the president, who reviewed the work of the College during the past year, and indicated the lines of development which the council hoped to pursue in the coming year. He emphasized the fact that, while the chief work of the College and of the council must be towards the betterment of the practice of obstetrics and gynaecology, it was believed by many that the outward and visible signs of the existence of the College were important. For this reason the council had obtained a patent for coat of arms and crest which, he understood, was cordially approved by all as being dignified and appropriate. Gowns had been designed for the use of Fellows and Members, and these had been worn for the first time at the admission ceremony of new Fellows and Members on the previous day. More important still, he believed, was the provision of a central home in London, a home which would be not only a centre for the business of the College, but where the Fellows and Members could meet each other, and where the commencement could be made of what he hoped would become the finest obstetrical and gynaecological library in the country, a home in which all could take pride and to which all could bring some offering, if only a book or a piece of antique furniture. The realization of this had been considerably advanced by the munificent gift which he was now able to announce from Lord Riddell. Fellows and Members would remember that Lord Riddell had very generously given the sum of £1,000 when the College received incorporation, and he had now made a further gift of £600 per annum for seven years.

In seconding the adoption of the reports, the honorary treasurer, Mr. Eardley Holland, called attention to the fact that a home in London worthy of the College would, in the future, require a considerably greater income than the College at present obtained, and it would be necessary to establish an endowment and a building fund. At the present time it did not seem propitious to launch a big appeal, but when the trade of the country improved, which he hoped would not be far distant, he proposed to open an appeal for both these funds.

A meeting of the new council was held immediately after the annual general meeting, when the following officers were unanimously elected. President, Professor W. Blair Bell (Liverpool); honorary treasurer, Mr. Eardley L. Holland (London); honorary secretary, Professor W. Fletcher Shaw (Manchester).

The following standing committees were also elected: Finance and Executive Committee—the president, honorary treasurer, and honorary secretary, Dr. T. Watts Eden, Sir Ewen J. Maclean, and Mr. L. C. Rivett; Examination Committee—Dr. H. Russell Andrews, Dr. J. S. Fairbairn, Professor R. W. Johnstone, Dr. R. A. Lennie, Dr. Bethel Solomons, Dr. J. E. Stacey, Professor Miles H. Phillips, and Professor Beckwith Whitehouse, with the president, the honorary treasurer, and the honorary secretary *ex officio*; Fellowship Selection Committee—the president, Professor A. Donald, Dr. T. Watts Eden, and Professor J. M. Munro Kerr.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD

Medical Scholarships

The London Inter-Collegiate Scholarships Board announces that an examination for six medical scholarships and exhibitions, and one dental scholarship, of an aggregate total value of £538, will commence on June 16th. They are tenable at University College and University College Hospital Medical School, the London (Royal Free Hospital) School of Medicine for Women, and the London Hospital Medical College. Full particulars and entry form may be obtained from the secretary of the Board, Mr. S. C. Ranner, M.A., the Medical School, King's College Hospital, Denmark Hill, S.E.5.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—H. T. Giblin, H. A. T. Wells.

MEDICINE.—L. Banszky, G. C. Brown, H. R. Fosbery, W. G. Kingston, A. E. Mathews, L. Sachs, G. Smith, L. C. H. Sykes, H. W. Toussaint, C. D. Trimble, P. Wade.

FORENSIC MEDICINE.—H. M. El Magidi, W. Hertzog, J. S. Lane, F. G. Leekam, C. D. Trimble, C. F. Vieyra.

MIDWIFERY.—G. Handelsman, S. Lokecz, C. Morgan, R. Pakenham-Walsh, S. Ramarao.

The diploma of the Society has been granted to Messrs. G. C. Brown, H. R. Fosbery, W. G. Kingston, J. S. Lane, L. Sachs, L. C. H. Sykes, C. D. Trimble, and P. Wade.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

On April 30th the House of Lords read the Pharmacy and Poisons Bill a third time without debate. Formal amendments were made in the measure. The Bill has been received by the House of Commons and printed as it left the Lords. Notices for its rejection have been given by Mr. Graham White and Mr. Bennett. It was set down for second reading on May 11th, but may not be taken till later. An invitation was issued for interested M.P.'s to hear members of the Pharmaceutical Society explain their objections to the Bill in a room at the House of Commons on May 7th.

The House of Commons, on May 1st, gave a third reading to the Local Authorities (Publicity) Bill and to the Marriage (Prohibited Degrees of Relationship) Bill.

Moving, on May 4th, a resolution to authorize the levying in 1934, and subsequent, of a land value tax, Mr. Snowden said the sites of hospitals and of almshouses would be exempt from this tax.

Smoke Abatement

On April 28th, in the House of Lords, Viscount MERSEY asked the Government what measures were being taken to deal with smoke abatement. Lord PARMOOR said that the difficulties in the way of a solution of the pollution of the atmosphere arose largely from the use of the domestic coal fire. Anxious as the Government was that this atmosphere pollution should be dealt with, there seemed little prospect at present of obtaining powers over the domestic hearth which would really be of use in bringing about a reform in what was an ever-increasing danger. Many experiments were being carried out on the technical side. On the administrative side, attempts had been made by one or two authorities to frame by-laws under the Act of 1926, but they had had to be rejected because of the difficulty of obtaining convenient and reliable measures of the density of smoke. They must have a scientific power of discernment before they could make by-laws of this kind really effective, and experiments on this point were being conducted at the Fuel Research Station at Woolwich. Although he would like to think that there would be no further delay in dealing with smoke abatement, at present the Government could not undertake further work in that direction. The two departments concerned were doing all they could.

Lord NEWTON said that, while fogs were not as bad as formerly, they were just as prevalent. The damage which a really bad fog could do was illustrated by what happened recently in Belgium. It was conceivable that some day the same thing might occur here. The truth was that we could not enjoy the amenities of burning raw coal in an open fireplace without contributing to the dirt, discomfort, and smoke with which we were periodically afflicted. If the Government were in earnest they should insist on the provisions of the Act of 1926 being enforced.

The Earl of ONSLOW urged the Minister of Health to exercise the greatest vigilance over local authorities. Where possible, they should insist on the Act being carried out.

Lord COZENS-HARDY said that the Government and local authorities might discourage the fixing of open fireplaces in subsidy-built houses.

Animal Experiments

Mr. FREEMAN, on April 28th, asked Mr. Shaw the number of experiments, and of the animals involved in them, in each of the chemical research laboratories in 1930. Mr. SHAW replied that he understood that Mr. Freeman used the term "experiment" to cover a single investigation in which one or more animals might be used, and the figures which he now gave were on that basis. The number of experiments carried out at the Chemical Defence Experimental Station, Porton, during 1930, and the number of animals involved, were 131 and 719 respectively; the number of animals involved in experiments at the Physiological Laboratory, Cambridge, during the same period, was 85. Exact figures as to the number of experiments at Cambridge were not available at the War Office. The largest number of animals involved in any one experiment since the opening of the Chemical Defence Experimental Station, Porton, after the war, was 92. The experiment was carried out in August, 1924, with the object of ascertaining the effect, if any, produced by exposure to low concentrations of gas.

Small-pox

On April 30th Mr. GREENWOOD said that, during the year 1930, 280,075 certificates of successful primary vaccination of children under 14 years of age and 293,176 statutory declarations of conscientious objection were received by vaccination officers in England and Wales. These figures were exclusive of a few returns not yet received. During the same period, among children under 14 years of age, thirteen deaths occurred which were classified to small-pox, and three deaths in which the words "vaccination," "vaccinia," or "post-vaccinal encephalitis" appeared on the medical or coroner's certificate. One other death associated with vaccination had been brought to the notice of his department. Mr. Greenwood added that he was still considering the whole question of the administration of the Vaccination Acts.

Replying to Mr. Freeman, on April 29th, Dr. SHILLS said there were in Northern Rhodesia, in 1928, 4,042 cases of small-pox and 267 deaths, and in 1929 3,856 cases and 302 deaths. Figures for 1930 had not been received. For Southern Rhodesia the figures were: in 1926 1 case, no death; in 1927 10 cases and 1 death; in 1928 255 cases and 5 deaths; in 1929 431 cases, the number of deaths being unknown. Figures for 1930 had not been received.

Royal Commissions and Health

A list of Royal Commissions, other Commissions, and committees appointed by the present Government was circulated with the parliamentary report for April 30th. Among the committees enumerated are the Local Government and Public Health Law Consolidation, appointed on December 8th, 1930, to consider under what heads the enactments applying to England and Wales, exclusive of London and dealing with matters relating to the public health, should be grouped in consolidating legislation; Advisory Nutrition, appointed on January 6th, 1931, to advise the Minister of Health on the practical application of modern advances in the knowledge of nutrition; Industrial Assurance, appointed on April 13th, 1931, to examine and report on the law and practice relating to industrial assurance and to assurance on the lives of children under 10 years of age.

These three committees have not reported.

Bills.—In the House of Lords, on April 28th, the Workmen's Compensation Bill was introduced by Lord MARLEY, and read the first time. The House of Lords, on April 28th, agreed to the Commons amendments to the Yarmouth Naval Hospital Bill.

Royal Veterinary College.—Dr. ADDISON, replying to Sir William Jenkins on May 4th, said that his Department made annual maintenance grants of £3,300 to the Royal Veterinary College, Camden Town, and £2,850 to the School of Veterinary Science at Liverpool. These grants were fixed block grants for a period of five years, and the amount in each case was now under reconsideration. There were 200 students at the Royal Veterinary College and 61 at the Liverpool School.

State Scholarships.—Correcting a reply which he had given in the previous week, Mr. LEES-SMITH told Mr. Somerville Hastings, on April 20th, that though State scholarships from secondary schools enabled their holders to take up courses for degrees in medicine or dentistry, the maximum period for which such a scholarship could be held—namely, four years—was not sufficient to cover the whole course required for professional qualification in these subjects.

Change of Doctor.—Replying to Mr. Albery, on April 30th, Mr. GREENWOOD said an insured person who, at the commencement of a quarter, felt he could no longer accept medical attendance from his insurance practitioner and had been refused by that practitioner consent to transfer, would normally be expected to apply for any necessary treatment to the insurance doctor on whose list he remained during the remainder of the quarter until the transfer was effected by giving one month's notice to the Insurance Committee. If such a person applied for treatment to another doctor, any charges for such treatment would not be payable out of insurance funds. In accident or other sudden emergency, application could be made by the insured person to another insurance doctor for treatment at the cost of insurance funds, if the doctor on whose list he remained, or his deputy, were not available. Mr. Greenwood said he realized that persons desirous of changing their medical adviser were involved in expenses during the period of notice, but the approved societies had themselves agreed to the new arrangement with regard to the choice of doctors.

Appeals by Insured Persons.—Mr. GREENWOOD told Mr. Albery, on April 30th, that the procedure to be followed by panel patients who wished to appeal against a decision by a regional medical officer was laid down in the rules of each society. He had no reason to think that such procedure ordinarily caused undue difficulty to the insured person, or that any general revision was called for. He would look into any case where an insured person had had difficulty.

Funds of Approved Societies.—Replying to Mr. Remer, on April 30th, Mr. GREENWOOD said the sum of £127,000,000 which stood to the credit of the National Health Insurance Fund was represented in the main by the funds of approved societies. It was required to supplement contributions as the insured grew older and the claims for sickness and disablement benefits increased, to meet the cost of additional benefits provided wholly out of surplus capital as ascertained on valuation, and to cover the cost of medical benefit after the age of 65, when contributions ceased. Replying to Sir Kingsley Wood on the same date, Mr. Greenwood said a general report by the Government Actuary on the results of the third valuation of approved societies would be presented to Parliament as soon as possible after the completion of that valuation. He could not fix a date for this.

Insurance Pharmacists.—On May 4th Lieut.-Colonel HOWARD-BURY asked the Minister of Health if the Government had come to a decision to introduce legislation to repeal the clause which prohibits insurance chemists from giving an insured person an inducement, by gift or otherwise, in consideration of his presenting an order for drugs or appliances on a national health insurance form. Miss LAWRENCE replied in the negative, and added that legal proceedings on the matter were still impending.

Pensions Hospitals.—Mr. F. O. ROBERTS informed Sir A. Pownall, on May 4th, that there were seven hospitals in the occupation of the Ministry of Pensions which were the property of the State, apart from hospitals held on lease for short or long periods.

Free Milk for Children.—Mr. LEES-SMITH told Mr. Freeman, on April 30th, that approximately 50,000 children were being supplied daily with free milk, at a cost estimated at £2,000 to £3,000 per week. He did not contemplate any increase in the percentage of this expenditure to be borne by the Exchequer, and he encouraged local authorities to make provision of free milk by regarding this as medical benefit and paying the special grant for medical purposes

Obituary

SIR BYROM BRAMWELL, M.D., LL.D., D.C.L.

F.R.C.P.ED. AND LOND., F.R.S.ED.
Consulting Physician, Edinburgh Royal Infirmary

A great physician of a former generation has passed away with the death of Sir Byrom Bramwell, on April 27th, at his residence in Edinburgh. Sir Byrom was in his eighty-fourth year, and had been in failing health for some time. He was born in 1847 at North Shields, where his father and grandfather had conducted a medical practice before him. His father having studied medicine at Edinburgh, Byrom Bramwell went to the University filled with the medical traditions of the place, and, after a distinguished undergraduate career in which he gained seven class medals, he graduated M.B. with honours in 1869. As a student he took a great part in athletics, and for one year captained the University cricket eleven. Following a period spent as house-surgeon to the late Professor Spence, he was invited by Professor Laycock to become his assistant in the chair of medicine, but, having determined to take over a practice and assist his father in North Shields, he was compelled reluctantly to decline this post. Immediately on settling in North Shields he obtained a number of local appointments, and for four and a half years was busily engaged in conducting a large private practice.

He had always cherished the ambition to become a teacher of medicine, and in 1871, being appointed lecturer on medical jurisprudence and on pathology in the University of Durham, he moved to Newcastle. Here he had ample time to devote himself to research and writing, and in 1874 was appointed physician and pathologist to the Royal Infirmary of Newcastle. In 1877 he presented a thesis for the M.D. degree of Edinburgh entitled "Reports on Clinical Cases," and was awarded a gold medal. Two years later, in pursuit of his early ambition, he resigned his appointments and practice in Newcastle and moved to Edinburgh, with the intention of lecturing on medicine and practising as a consulting physician. Here he immediately introduced a new idea in starting a class upon medical diagnosis in the extra-academical school. This class, which was purely voluntary, attracted students in such large numbers that other teachers followed his example by instituting similar courses. In 1880 he became a Fellow of the Royal College of Physicians of Edinburgh, and began a regular course on medicine qualifying for graduation, which he continued with marked success during the greater part of his active life.

After acting for three years as pathologist to the Royal Infirmary of Edinburgh, he became an assistant physician in 1885, and in 1897 was promoted to the post of physician to the institution. From 1892 to 1897 he lectured on clinical medicine to the women students, who were at that time taught separately from the men, and during this period he began to give weekly out-patient clinics to the male students, which became celebrated as his Saturday clinics. The novelty and attractiveness of these clinics drew the students in large numbers, and for several years they were published fortnightly as a brochure called *Studies in Clinical Medicine*. When he became a physician in charge of wards, he revived these clinics on Wednesdays, and published an account of them as a quarterly journal called *Clinical Studies*, that appeared for eight years, from 1903 to 1910, and had a very wide circulation among students and practitioners. These Wednesday clinics were conducted in a small classroom under Ward 28, known colloquially as the "Duck-pond," where every available inch of room was filled by an audience of students, usually numbering some two hundred, and they formed one of the most popular features of the Edinburgh Medical School.

In addition to strenuous work as a physician to the Royal Infirmary and constant labour in research, recording, and writing, Byrom Bramwell was for many years one of the busiest consulting physicians in Scotland. On the death of Sir Thomas Grainger Stewart in 1900, Bramwell became a candidate for the chair of medicine at Edinburgh University, and it was a great disappointment to students and to his many friends in the profession that he failed to secure this coveted position. He continued his work of teaching and writing, however, with unabated zeal.

During thirty years, from the time when he started practice in Newcastle to the end of the century, more than 160 communications to medical literature had issued from his pen, many of them of the first importance. In the period while as a young man he was waiting for practice at Newcastle, the *Transactions* of the Northumberland and Durham Medical Society were almost filled with his observations on clinical and pathological subjects. His book on *Diseases of the Spinal Cord*, published in 1881, had appeared in lecture form in that periodical, and it is richly illustrated by sections and drawings, chiefly made by his own hand. It attained a great success, and was translated into German, French, and Russian, while several editions were reproduced in America. His *Diseases of the Heart and Thoracic Aorta*, published in 1884, was largely a record of personal experience, both clinical and pathological, and again its numerous illustrations were mainly derived from his own work. This book attained a great success in its time, but, being produced immediately before what may be called the instrumental epoch of cardiology, it is not now consulted as much as its usefulness deserves. *An Introduction to Practical Medicine and Medical Diagnosis*, published in 1887, formed the record of his successful innovation of a class on this subject at Edinburgh. *Intracranial Tumours*, published in 1888, has become one

of the classics of medicine, and regarding this work Dr. Harvey Cushing of Boston, in his 1930 Lister Memorial Lecture, remarked: "It has been said that if some unusual clinical condition turns up concerning which one seeks information, an account of it is likely to be found in Jonathan Hutchinson's *Archives*. To this I would like to add, particularly for the benefit of neurologists, that if Hutchinson fails them, try Byrom Bramwell." In this book, too, Bramwell was the first to draw attention to the connexion of tumours of the pituitary body with an excessive development of fat and the presence of diabetes. The *Atlas of Clinical Medicine*, in three large volumes illustrated by many coloured plates which were prepared under Bramwell's personal supervision, was issued between 1892 and 1896. In the first volume occurs an interesting statement with regard to myxoedema, that in 1869 (that is, four years before Sir William Gull first described this disease) Bramwell's father had pointed out to him a case showing all the essential features of this disease, and had remarked that this was a new disease—a disease which had never been described. He regrets, however, that no written description of the malady was then published by his father or himself. The *Lectures on Aphasia*, published in 1897, and based upon cases which had occurred in Bramwell's own experience, did much to elucidate the nature of this condition and explain its varieties at a time when the subject was still being handled to a great extent by the "diagram makers." His work *Anaemia and Diseases of the Blood-forming Organs*, published in 1899, was a comprehensive account of what was then known on this department of medicine, and it may be recalled in this connexion that he was the first, in 1875, to introduce the arsenical treatment of pernicious anaemia.

Other contributions to medical knowledge and practice are to be found in his shorter writings. Thus he was the first, in a paper read to the Northumberland and Durham Medical Society in 1872, to describe the transmission of scarlet fever by milk supply. For a long time before its introduction he was a strong advocate of the compulsory notification of phthisis, and in 1893 he first introduced the thyroid treatment of psoriasis and other skin diseases, a practice which has been extensively followed by dermatologists. In 1902 he first described a condition of infantilism due to pancreatic defect. For some thirty years, as a teacher of medicine and clinical medicine, as a clinician, and as an investigator of pathological problems, he was one of the strongest and most outstanding figures in the Edinburgh extra-academical school, and he attained a reputation which was world-wide.

Honours naturally came to him. The Universities of Edinburgh, St. Andrews, and Birmingham conferred on him their honorary LL.D. degrees, and from the University of Durham he received the degree of D.C.L. In 1886 he became a Fellow of the Royal Society of Edinburgh, and was for several years a member of its council. He was chosen to deliver the Morison Lectures in the Royal College of Physicians of Edinburgh in 1899, and in 1910 he was elected president of that College. He took much interest in the work of the British Medical Association, was a member of the Edinburgh Branch Council in 1888, and president of the Branch in 1908. He held the office of secretary of the Section of Medicine at the Annual Meeting of the Association at Liverpool in 1883, and presided over the same Section at Cardiff in 1885, and was president of the Section of Neurology at Edinburgh in 1898. He became president of the Medico-Chirurgical Society of Edinburgh in 1909, and president of the Association of Physicians of Great Britain and Ireland in 1923. In the same year he was elected, under By-law XXXVIII (*b*), a Fellow of the Royal College of Physicians of London, and at this time his friends and former pupils took occasion to present him with his portrait, painted by Mr. David Alison. In presenting this portrait, Sir David Drummond referred to "the warmth and generosity of the references made by medical men all over the world to the debt of gratitude they owe him as their clinical teacher, and for acts of kindness and encouragement received at his hands when they were students"; and Sir Humphry Rolleston, in presenting a replica of the portrait to the College of Physicians, remarked that "to recite what he has done for medicine would be a task like reading an address on the modern advances of the last forty years." In the following year Byrom Bramwell received the honour of knighthood for his services to medicine. Foreign societies, especially those connected with the branch of medicine in which he had taken a special interest, united in conferring on him their honorary membership. Thus he was a corresponding member of the Neurological Societies of Paris and Philadelphia, and of the German Neurological Society, and an honorary member of the Société des Médecins Russes de St. Petersburg, of the American Neurological Association, and of the Manchester Medical Society.

Sir Byrom Bramwell was an outstanding clinician among a group of great physicians, an eminently successful teacher in a medical school whose special tradition has been the imparting of knowledge to students, and a friend, true, sympathetic, and ever ready with help, to those who had the privilege of knowing him.

In 1872 he married Martha Crighton, daughter of Edwin Crighton of North Shields, who predeceased him. He is survived by three sons, of whom two are well-known physicians, and by a daughter. A memorial service was held in St. Mary's Episcopal Cathedral, Edinburgh, on April 30th, at which were present representatives from the University of Edinburgh, the Royal College of Physicians of Edinburgh, the Board of Managers of the Royal Infirmary, and the Scottish Union and National Insurance Company (to which Sir Byrom Bramwell had been for many years medical consultant), as well as many members of the medical profession in Edinburgh. The funeral was private.

Sir DAVID DRUMMOND writes:

It has been my great privilege to enjoy the friendship of Byrom Bramwell for a period of fifty-five years, dating back to the Newcastle days, when we worked together in the wards of the old Royal Infirmary, and it is a duty one owes to his memory to acknowledge the very great service his method and enthusiasm as a clinical teacher was to the Newcastle School of Medicine. To me personally his earnestness and industry, and his keen appreciation of the wealth of clinical material to be found in the wards, were a revelation, and one could not help being inspired by his enthusiasm. It was, of course, a great loss to Newcastle when he went to Edinburgh, but he had left his stamp, which is to be recognized to-day in the wards of the Royal Victoria Infirmary. He is long to be remembered as one of the greatest clinicians of our time, but to me his reputation as a physician is overborne by the memory of a loyal and warm friend, whom to know intimately was to love and to admire.

Dr. ROBERT HUTCHISON writes:

To many Edinburgh men scattered all over the world the death of Byrom Bramwell must have seemed like the breaking of a link with the past. He was one of the few survivors of a brilliant band of teachers in the extra-mural school of the university towards the end of last century, and it was to him more than anyone that many students owed their best teaching in clinical medicine. The Edinburgh school has always been fortunate in its lecturers, but it was not in the lecture room that

Bramwell's great gifts showed to most advantage. He was pre-eminently a clinical teacher, and was always happiest in the out-patient room or at the bedside. Many of his old students must have a vivid recollection of his Saturday morning out-patient clinics. He was seen in these at his very best, and the keen and accurate observation which he showed, and his brilliant and sometimes dramatic demonstration of cases, were a lasting inspiration to his audience. But although such an outstanding teacher, there was nothing dogmatic or pontifical about Bramwell, for he was eminently approachable, and would discuss a case with the most junior student as with an equal, and he has been known, when at a complete loss for a diagnosis—which did not happen often—to appeal to any member of the class for a suggestion. It was this real simplicity as much as his great intellectual gifts which gave him his influence as a teacher.

Byrom Bramwell was a type of physician now becoming rare, for although his special leanings were towards neurology, yet he touched medicine at all points, and wherever he touched he adorned. This catholicity of interest is shown in his well-known *Atlas*, and also in his *Clinical Studies*, although it will probably be for his work in neurology that he will be best remembered. He lived to an advanced age, but his keenness never failed, and to the end of his long life he was still intensely interested in the latest advances of our science and in any suggested improvements in the teaching of students. Full recognition came to him late, but it came at last in unstinted measure, and he was the recipient of many honours. What probably gave him most pleasure, however, was the presentation to him a few years ago of his portrait, subscribed for by former house-physicians and old students. It was a spontaneous testimony of esteem by which he was much gratified. He was happy in his long life of active work and in the leisure of the long evening of his days; he was happy in the affection of his family and in the veneration of his pupils; but perhaps he must be accounted happiest of all in the example he has left behind him.

Dr. S. A. KINNIER WILSON writes:

No one who in other years was associated closely with Dr. Byrom Bramwell, as he then was, as senior student, house-physician, or assistant, is ever likely to forget the immensely stimulating influence of contact with him. At a time when the Edinburgh school was adorned with a number of distinguished men on the medical side, when its reputation was supreme and its classes thronged, Bramwell easily took his place in the front rank of students' favourites. To come under the spell of his clinical teaching was a liberal education. Big, kindly, critical, unruffled, he handled large clinics with masterly control and sure insight. From a rich store of experience came illustrations to throw light on cases before his audience, who followed closely his descriptive expositions, and whose attention was held by little touches of personal reminiscence or by allusions to the pioneers of neurology in England, among whom, indeed, his own place is. For he was old enough to be able to remember a time when the nervous system was nought else than a *terra incognita*, and when clinical knowledge of nervous disease had neither sound neuro-pathology nor adequate experimental physiology to support it—a time not far removed from the era of "lucky guesses" of which the late Sir David Ferrier used to speak with pity and scorn. Bramwell's enthusiasm for his own subject, and the untiring energy and zeal with which he pursued it, were such as deeply to impress any young and receptive mind whose bent, consciously or not, lay in the same direction. Memory recalls the fascination cast over these first days of exploration in neurology, when each case was a novelty and each provided a problem in clinical study. The acuteness of observation and shrewd assessment of the patient's personality exhibited by Bramwell are still cherished by those of us who worked with him as incentives for ourselves, to emulate, copy, and evince, if possible, to others of a younger generation. From the past there comes vividly into the mind a picture of a Sunday morning hospital round, when he was told a new case had been admitted, and as we reached the bedside he looked and said, "Ah, I see it's one of general paralysis." What need to detail the immediate summation of clinical appearances enabling the diagnosis to be made as by a single glance? The certainty becomes none the less remarkable because we have learned how it was attained. The affectionate interest with which he followed the careers of those who had belonged to the select group of residents and assistants remained with him to the end. Dinners at his town or country house, games of bridge, talks far into the night, bound us to him in a way one does not need to elaborate. If his house-physician was speciously dubbed by fellow residents "Keeper of the Freaks," it mattered not at all, for who in those days *did take particular notice of neurological flotsam and* jetsam? In the streets of the city we were wont to see sufferers whose distressing features were exposed to the passer-by in a fashion long since put an end to; and the fact that Bramwell was of the few who saw the scientific significance of their cases as he felt their personal degradation is what then endeared him, as still in memory it does, to those who had eyes to see. Retired for a considerable time from active participation in hospital work, his charm of person and wealth of mind were bound to become less known save to his intimates, so that ere long only the tradition of his renown lingered with those that loved him. To convey even an imperfect idea of all that Bramwell meant in the lives of his junior associates is no easy task, but he is enshrined in their hearts as a beloved "chief."

> What practice howsoe'er expert
> In fitting aptest words to things,
> Or voice the richest-toned that sings,
> Hath power to give thee as thou wert?

Professor W. T. RITCHIE writes:

By the death of Sir Byrom Bramwell medicine loses a most distinguished exponent and the Edinburgh Medical School one of her greatest sons. Universally honoured as a physician and teacher, he was regarded with the veneration that is justly accorded to an eminent man in the evening of life. A disciple of the father of clinical medicine in England, Sir Byrom was a great physician in the true sense of the term, for he was the very beau-ideal of "the physician as naturalist." His chief work lay, it is true, in the domain of neurology, on which he was a foremost authority; yet his interests extended throughout the whole realm of internal medicine, and the numerous publications in which he widened the frontiers of knowledge regarding the diseases of the blood and heart, the thyroid, pituitary, and other endocrine organs received world-wide recognition, and, like his monographs on disease of the nervous system, are classic.

As a consulting physician Sir Byrom stood in the very forefront, not only because of his intellectual attainments and scientific eminence, but also inasmuch as his professional colleagues knew that in him implicit trust and confidence could be reposed. A clinician of vast experience, most impressive manner, and extraordinarily sound judgement, he had the true clinical instinct of recognizing and interpreting the essential while disregarding the immaterial. In an incredibly short time he would solve

the problem of a difficult case; his opinion regarding diagnosis, prognosis, and treatment was authoritative; he was the final court of appeal. As a clinical teacher he excelled. In that sphere he had few equals; none surpassed him. All who were studying medicine in Edinburgh a generation ago will have vivid recollections of his profound clinical acumen and masterly skill as a teacher. Every Saturday morning one of the clinical medicine theatres was crowded by an audience of some two hundred final-year students, who were attracted by Sir Byrom's demonstration and exposition of medical cases. He would present five or six patients illustrating diseases of the nervous, cardio-vascular, haemopoietic and other systems, and held his hearers' attention so closely, and interested them so keenly, that they were astonished to find the hour's demonstration drawing to an end. His teaching was strictly scientific, yet dogmatic and intensely practical. Students never forgot what he had taught them; each disease as he had presented it was remembered as a well-defined clinical picture. He had the rare gift, too, of arousing his students' enthusiasm in those subjects in which he himself was so deeply interested. In the Royal Medical Society they read all the available literature upon the subjects that he had been demonstrating, and so convincing was his teaching that the written word was unhesitatingly rejected if it did not agree with that spoken by Sir Byrom.

My earliest recollection of Bramwell is of a young, burly, handsome man and fond parent, joining in the gaiety and fun of children's parties to which I, as a friend of his eldest son, was invited. Ten years pass, and I recall the brilliant clinical teacher, at whose feet we Edinburgh students sat, and whose words of wisdom we treasured. For a brief period thereafter he was my chief, and then I first realized his orderly methods and untiring capacity for work. He invested his house-physicians with full responsibility during the hours when he was not in the hospital, and never worried them with petty detail. His country home was then that picturesque old mansion, Braehead, of historic interest for its romantic association with Jock Howison and King James V. A few years later, when residing at Baberton House, he spent many a happy evening on Threipmuir, one of the beautiful little lochs nestling at the foot of the Pentlands, in the heart of the Stevenson country. Though fond of a game of bridge on a winter's night, his favourite recreation was a day with his rod on river or loch. For many a year one of the noteworthy events was the annual competition on Loch Leven between the staff of his wards and those of Dr. George Gibson, each side captained by the chief.

At no time did Sir Byrom devote his thoughts and energies to medical politics. With the passing years he presided with quiet dignity over the deliberations of the Royal College of Physicians of Edinburgh. The memorable events at the meeting of the Association of Physicians in Edinburgh some years later, when Sir Byrom was president, were his remarkably able summing-up of each discussion and the fishing stories that he told at the dinner. As a Nestor of the medical profession he was on that occasion presented in the hall of the College with his portrait, a symbol of the esteem and affection of his friends, among whom was Sir David Drummond, his life-long friend. Until the close of his life Sir Byrom continued to take the keenest interest in every fresh advance of medical science and education. Full of years and honours he has passed within the veil. We think of him, "our master, famous, calm, and dead," in the assurance that his name will ever be linked indissolubly with those of his illustrious intellectual forebears in the medical school he so richly adorned.

WALTER TYRRELL, M.R.C.S.

Consulting Anaesthetist to St. Thomas's Hospital

A familiar figure in South Kensington, in the person of Walter Tyrrell, passed away on April 21st. The son of a county court judge at Exeter, Tyrrell came from the West Country and entered St. Thomas's in 1872, with the idea of adopting dental surgery as a profession. He soon abandoned his original intention in favour of general medicine, and after qualifying and serving as house-physician at St. Thomas's in 1879 started practice on his own behalf in the Cromwell Road, where he remained until he retired some fifteen years ago. He retained a direct connexion with St. Thomas's as an anaesthetist for many years. He, together with Mr. S. Osborn, was the first special officer appointed to the staff as anaesthetist. Tyrrell commenced under the influence of Sir Victor Horsley with a decided preference for the use of chloroform, but later devised an ingenious double-bottle apparatus for the administration of chloroform and ether in combination. He was a most efficient anaesthetist, greatly relied upon by his colleagues, never giving them a trace of anxiety even in the most troublesome cases. His services were much sought after, and he acquired a very extensive connexion, which he succeeded in maintaining while developing at the same time a wide and successful general practice.

Sir GEORGE MAKINS writes:

As a medical attendant Tyrrell was greatly esteemed. Fully competent to deal with any case, his quiet and confident bearing inspired absolute trust, while his kindly and sympathetic nature often converted those who came to him as patients into lifelong friends. The transparent honesty of purpose and genial nature which gained for him success in practice accounts also for the excellence of the relations which existed between him and his fellow practitioners, whom he did much to bring together in friendly contact. With his friend and contemporary Dr. Kingston Barton, and Dr. Culver James, Colonel I.A.C., he took part in founding the Kensington Medical Reading Society, of which he became the secretary, and he was one of the original members of the West London Medico-Chirurgical Society. It is difficult to imagine Tyrrell having an unfriendly difference with anybody. Until 1904 he worked singlehanded in association with Dr. Kingston Barton, but in that year, beginning to feel the labour and responsibilities of a large practice a little too much for him, he took Mr. (now Sir Robert) Fox-Symons into partnership, and in 1912 he relinquished his work.

Although a man of cultured tastes Tyrrell in his busy life had cultivated no special hobbies, and he retired into the country at Shottermill with the idea of resuming some of his youthful interests. Ultimately he returned to London, and his health had improved so much that many of his friends regretted his somewhat premature retirement. For the last four years, however, he had been in very bad health, and his death on nearly exactly his eightieth birthday came to him as a happy release. Soon after he settled in practice he married Miss Sara Bevan, who proved herself a delightful and most sympathetic wife to him, of very great service in every detail of their lives. Mrs. Tyrrell and their two daughters survive him.

Dr. GEORGE DUNCAN MORRISON BEATON, one of the best-known surgeons in North-East Lancashire, died at Accrington on April 14th at the age of 49. He was a native of Stornoway, and was educated at the Nicolson Institute and Glasgow High School. He took the Scottish triple qualification in 1905,

and graduated M.B., Ch.B.Glas. in 1906. After a period as house-surgeon in Glasgow Royal Infirmary he went to Accrington in 1908, and built up a large medical and surgical practice. He was surgeon to the Accrington Victoria Hospital for twenty-one years, and on his retirement from the post of senior surgeon to that institution in 1930 he was appointed consulting surgeon. During the war Dr. Beaton served in the R.A.M.C., and later with the R.A.F.M.S. He was wounded in the advance of October, 1918. On his return from active service, in addition to resuming his hospital work and large practice, he did valuable work under the Ministry of Pensions, being chairman of the pensions medical board and senior surgical specialist for the Blackburn area. He was an active member of the British Medical Association, and in 1925 was elected chairman of the Blackburn Division. Notwithstanding the heavy demands of his professional work, Dr. Beaton found time to take an interest in local affairs. He was a member of the Accrington Town Council from 1922 to 1928, and rendered useful service on the educational and maternity and child welfare committees. Dr. Beaton was a man of many friends, both in his profession and outside it. His extensive practice testified to the esteem in which his services and advice were held. There is no doubt that his devotion to his work undermined a constitution once robust, and his death at an early age is an irreparable loss to Accrington and district. He was laid to rest in Carlisle Cemetery on April 17th. He leaves a widow and one daughter.

The following well-known foreign medical men have recently died: Professor FRANZ ENGEL-BEY, an eminent leprologist and director of the medico-statistical department of the Egyptian Health Office, aged 81, at Berlin; Professor MENDELSOHN, formerly of the chair of physiology at St. Petersburg, and later physician to the Russian Imperial Court, corresponding member of the Académie de Médecine; Dr. CONRAD HEMMETER, emeritus professor of the Maryland School of Medicine, Baltimore, and formerly president of the American Gastro-Enterological Association, aged 67; and Dr. C. YOKOTE, professor of Hygiene in the Tokyo Imperial University.

The Services

DEATHS IN THE SERVICES

Major-General George Francis Angelo Harris, C.S.I., Bengal Medical Service (ret.), died in London on April 16th, aged 75. He was born on February 29th, 1856, the son of Major-General George Shooter Harris, Bengal Staff Corps, was educated at Bedford School and at St. George's, and took the M.R.C.S. and L.R.C.P.Lond. in 1878. Subsequently he took the M.R.C.P. in 1893, was elected F.R.C.P. in 1903, and graduated M.D. of Durham in 1902. Entering the I.M.S. as surgeon on September 30th, 1878, he became lieutenant-colonel after twenty years' service, colonel on February 28th, 1910, and surgeon general on April 1st, 1912; the last title being changed to major-general in 1918. He served in the Afghan war in 1880, on the Khaibar Line, and received the medal. After a few years' military duty he entered civil employ in Bengal. While serving as second resident surgeon of the Presidency European General Hospital in Calcutta, in 1885, he was appointed joint civil surgeon of Simla, and after holding that post for five years, civil surgeon of Nagpur, the capital of the Central Provinces. In 1899 he was appointed to act as principal of the Medical College, Calcutta, first physician, and professor of medicine, and on the return from leave of the permanent principal, the late Sir Gerald Banford, K.C.I.E., was appointed professor of materia medica and second physician. In 1908 he was posted to act as inspector-general of civil hospitals in the Punjab, in 1909 to act in the same post in the United Provinces, and in 1910 was appointed inspector-general in Bengal. He retired on April 1st, 1915, and served from 1915 to 1917, as a retired officer, on military duty in England. He received the C.S.I. on December 11th, 1911, and a good service pension on May 25th, 1914. He was the author of a small book on the Bengal Medical Service, published in 1885. In 1883 he married Alice, daughter of General Archibald Edwards Campbell, B.S.C., and leaves a widow, two sons, and four daughters.

Colonel Charles Albert Maunsell, late R.A.M.C., died at Vence, Alpes Maritimes, France, on March 27th, aged 90. He was born on September 24th, 1840, and was educated at Queen's College, Galway, and at Trinity College, Dublin, taking the L.R.C.S.I. in 1861, and graduating M.D. of the Queen's University, Ireland, in 1862. Entering the Army as assistant surgeon on October 1st, 1862, he attained the rank of surgeon colonel on December 15th, 1892, and retired on September 24th, 1900. In the old regimental days he served in the Royal Horse Artillery. He was on the North-East Frontier of India in the Bhutan campaign of 1864-65, taking part in the capture of Fort Baksar (Buxa), the taking of the Bala Pass, the Tuzgaon stockade, and Fort Chamurchi, gaining the frontier medal with a clasp; in the Egyptian war of 1882 (medal and Khedive's bronze star), and in the Bechuanaland expedition under Sir Charles Warren in 1885. He took a large part in the struggle for improvement in the conditions of service of the private soldier in the 'eighties. He leaves three children, Colonel E. R. Maunsell, late Commandant of the 14th Prince of Wales Sind Horse, Captain I. O'G. Maunsell, late 91st Punjabis, and Mrs. Margaret Stella Prentice, whose son is now serving in the Sind Horse.

Lieut.-Colonel Hastings Norman Victor Harington, Madras Medical Service (ret.), died on December 12th, 1930. He was born on January 12th, 1855, the son of the Rev. Hastings Hawes Harington of Hourah, Bengal, was educated at Edinburgh and Aberdeen Universities, and took the L.R.C.P. and S.Ed. in 1879. Entering the I.M.S. as surgeon on October 2nd, 1880, he became lieutenant-colonel after twenty years' service, and retired on November 28th, 1910. After the usual two years of duty in the Army, he was appointed to the Political Department as an agency surgeon, and spent the rest of his service as agency surgeon in various Indian States, chiefly in Rajputana.

Medical News

Sir Charters Symonds and Dr. Robert Hutchison give notice, in pursuance of Section 115, Sub-section 1 (*c*), of the Companies Act, 1929, that an extraordinary general meeting of the members of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, Cavendish Square, W.1, on Monday, May 11th, at 4.15 p.m.

Lord Lloyd of Dolobran will preside at the annual court of governors of the Seamen's Hospital Society at the May Fair Hotel, W.1, on Tuesday, May 12th, at 3 p.m.

Two lectures on resection of the rectum will be given by Mr. G. Grey Turner, professor of surgery in the University of Durham, at St. Thomas's Hospital, on May 13th and 15th, at 5.30 p.m. Sir Percy Sargent will preside at the first lecture.

The Cavendish Lecture before the West London Medico-Chirurgical Society will be delivered at the Kensington Town Hall on Friday, June 5th, at 8.15 p.m., by Professor Julian Huxley; the subject of the lecture is "Development in relation to heredity and evolution." The annual dinner of the society will be held at the Trocadero Restaurant on Wednesday, July 1st.

The annual general meeting of members of the Optical Society will be held at the Imperial College of Science and Technology, South Kensington, S.W., on Thursday, May 14th, at 7.30 p.m. On June 11th Sir John H. Parsons, F.R.S., F.R.C.S., will deliver the Thomas Young Oration, taking as his subject the trichromatic theory of colour vision.

The annual general meeting of the British Institute of Radiology (incorporated with the Röntgen Society) will be held in the Reid-Knox Memorial Hall, at 32, Welbeck Street, W.1, on Thursday, May 14th, at 8.30 p.m. After the business part of the meeting is completed, a paper will be read by Mr. H. S. Souttar, on the ideal distribution of radon seeds.

The eighty-fifth half-yearly dinner of the Aberdeen University Club, London, will be held at the Trocadero Restaurant on Thursday, May 21st, under the chairmanship of Sir John Marnoch, and with Sir G. Lenthal Cheatle as chief guest. The honorary secretary's address is 9, Addison Gardens, W.14.

The Swindon Corporation's new maternity home in Kingshill Road will be opened by Mr. Arthur Greenwood, Minister of Health, on Wednesday, May 13th, at 3.15 p.m.

The annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 20th, at the Refectory, University College, Gower Street, W.C.1, at 8 a.m. An address will be given by Dr. Edward A. Hunter of Ilesha, Nigeria, West Africa. An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, Leyton, E.10.

The foundation stone of the new hospital for women at Papworth Village Settlement will be laid by the Right Hon. Arthur Greenwood, M.P., Minister of Health, on Tuesday, May 19th, at 2.30 p.m.

The second International Congress of the History of Science and Technology, to be held at the Science Museum, South Kensington, from June 29th to July 3rd, of which a preliminary announcement appeared in the *Journal* of March 31st, has now published a programme, illustrated by portraits of Isaac Newton, Charles Darwin, and Isaac Watt, and containing the names of the council and the aims of the congress. The following three subjects are chosen for discussion: (1) the sciences as an integral part of general historical study; (2) historical and contemporary interrelationship of the physical and biological sciences; (3) interdependence of pure and applied science. Furtner information can be obtained from the honorary secretary, Mr. H. W. Dickinson, Science Museum, South Kensington, S.W.7.

A Nursing, Hospital, and Health Week will be held in Edinburgh from May 25th to 30th inclusive in the Music Hall and Assembly Rooms, George Street. A comprehensive programme of lectures and discussions has been arranged. All medical men and women will be welcome on production of their visiting cards. On Sunday, May 24th, a special service will be held in St. Giles's Cathedral at 6.30 p.m. Further information may be had on application to the *Scottish Nurse*, 29, Cadogan Street, Glasgow, C.2, or to Mrs. Bowie, 10, Walker Street, Edinburgh.

Professor S. J. Cowell is giving a course of six lectures on medical aspects of dietetics in the lecture room attached to the dietetic kitchen of St. Thomas's Hospital. The first lecture was given on May 7th; the remainder will be given on succeeding Thursdays at 5 p.m.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found at page 832. The M.R.C.P. special evening lectures during the week will be as follows: May 12th, "Bone growth and metabolism: medical aspects of diseases of bones"; and May 15th, "Achlorhydria and anaemia." The lectures will take place at 8.30 p.m., at the Medical Society of London, 11, Chandos Street, Cavendish Square, and tickets may be taken at the door (10s. 6d. a lecture). Courses in June will include: gynaecology, at the Chelsea Hospital for Women; dermatology, at the Blackfriars Skin Hospital; diseases of children, at the Children's Clinic, and also at the St. John's Hospital, Lewisham; ante-natal care, at the Royal Free Hospital; cardiology, at the National Heart Hospital; and general medicine and surgery, at the Prince of Wales's Hospital. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

The forty-second Congress of the Royal Sanitary Institute will take place in Glasgow from July 4th to 11th, under the presidency of Sir Henry Mechan. Among the many subjects to be discussed are: The role of the hospital relative to the development of preventive medicine; the proposals of the British Medical Association for a general medical service, from the standpoint of preventive medicine, and in relation to national health insurance; development of the national health insurance scheme; administration of the Local Government Act, 1929; eugenic sterilization; health certificates before marriage; pregnancy and tuberculosis; and maternity and child welfare work. On July 10th Dr. Walter Elliot, M.P., will deliver a lecture on "A continuous health policy." A health exhibition has been arranged in connexion with the congress. The Lord Provost of Glasgow is the chairman of the local general committee, and the town clerk and the medical officer of health are acting as the honorary local secretaries.

Applications for the Rockefeller Medical Fellowships for 1931–32 must be sent to the Medical Research Council, 38, Old Queen Street, Westminster, S.W.1, not later than June 1st. The fellowships are awarded to graduates who have been training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and who are likely to profit by study at a university or some centre in the United States before taking up positions for higher teaching or research in the British Isles. In special circumstances the fellowships may be tenable at centres of research not in America. A fellowship held in America will have the value of not less than £300 a year for an unmarried Fellow, as well as travelling expenses and other allowances; there will be an extra allowance for a married Fellow.

A course on malariology, organized by the Health Committee of the League of Nations, will be held at the Hamburg Institute of Tropical Diseases from June 1st to July 4th, when lectures will be given by Drs. Fülleborn, Giemsa, Martini, Mayer, Mühlens, Nauck, Regendanz, Reichenow, and Weise. Further information can be obtained from Institut fur Schiffs- und Tropenkrankheiten, Berhard-Nochtstrasse 74, Hamburg 4.

A theoretical and practical course on urology will be held at the Hôpital Cochin, Paris, from July 20th to August 8th, under the direction of Dr. Chevassu. The fee is 500 francs. Further information can be obtained from the Amphithéatre d'Anatomie des Hôpitaux, Rue du Fer-à-Moulin 17, Paris.

"Medicine and science" is the title of an interesting editorial article in *Nature* for May 2nd, dealing with the problem of the evolution of medicine from a practical art to an applied science.

The *Daily Telegraph*, on May 6th, reproduced a photograph showing Dr. William Collier on his seventy-fifth birthday climbing, with three companions, the Pillar Rock in Lakeland. Dr. Collier is the senior Vice-President of the British Medical Association, and presided over the Annual Meeting at Oxford in 1905.

We have received the first issue of *Nutrition: Annales Cliniques, Biologiques, Thérapeutiques*, a bi-monthly review published under the scientific direction of Professors Carnot, Loeper, and Villaret, with Drs. R. Glénard and Mathieu de Fossey of Vichy as editorial secretaries. This first number contains seven articles, all of which deal with diabetes. The whole amounts to a compact and well-balanced treatise, for different aspects of the disease are considered in detail by each of the several authors. One deals with the pathology (from a chemical point of view), another reviews the evidence in favour of hepatic derangement as an important factor in the condition; other articles are devoted to a consideration of therapeutic measures, in which spa treatment and remedial exercises receive some attention. One of the most interesting is concerned with the types of what we should call "non-pancreatic glycosuria," and with the interrelationship of the different ductless glands, considered from the point of view of carbohydrate metabolism. There appears, as an appendix, a statement about the laboratories at Vichy, and some analyses of Vichy waters, and it would appear that the publication is issued in some way under the auspices of the authorities of that spa.

The French National Antituberculosis Society has published a statistical report for the year 1929, recording the general results of treatment in the registered dispensaries, and comparing the mortality figures for tuberculosis in all its forms in France and England. The booklet can be obtained from the offices of the Comité National de Défense contre la Tuberculose, 66, Boulevard Saint-Michel, Paris 6e.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Piercing the Lobule

"BARBARIAN" writes: I am occasionally asked to pierce the lobes of the ears for earrings. So far I have been unsuccessful in my attempts to maintain patency of the boring. Sepsis or other complications have resulted in complete healing of the areas. I have carefully read previous contributions in the *Journal* (1927, ii) on the subject of the operation of boring the lobule, but they do not help me much, as there is no reference to after-treatment, or guidance as to the best way of keeping the holes open. Would any reader enlighten me as to the most successful technique? I believe the operation is often performed by jewellers without ill effects.

Food Combinations

Mr. J. MENZIES CAMPBELL, D.D.S., L.D.S. (Glasgow) writes: Periodically one reads that "acid fruits and cereals should never be eaten at the same meal." The latest upholder of this view is Mrs. Lilian Lindsay, L.D.S., who expressed it definitely in a recent address to a conference of health visitors. I have tried, but failed, to obtain a satisfactory explanation of this statement, and I should therefore be glad if those in a position to do so would issue an authoritative pronouncement on the matter. If the above-mentioned food combination is bad, then the sooner this fact is made widely known the better; if, on the other hand, it belongs to the not proven category, then the sooner this, too, is made known the better. The advice which so many of us are giving to our patients is to eat fruit at meal times, and especially at the end of a meal.

Wagstaff's Forceps

Dr MICHAEL STARK (Wanstead Park, Essex) writes: In the *Journal* of April 18th "Croydonian" asks about Wagstaff's obstetrical forceps which my father recommended in his *Index to General Practice*. I have myself used them some hundreds of times, and found them all that could be desired. If your correspondent cared to ring me up (Wanstead 3017) and come here I should be pleased to show him mine.

Chromium Plating

Messrs MANN EGERTON AND CO., LTD., send the following note in reply to the inquiry about chromium-plated water-taps and metal fittings (May 2nd, p. 779): Chromium plating, which was introduced comparatively recently, has been extremely satisfactory in connexion with motor cars, and has, in fact, been adopted by practically every motor manufacturer. It is considerably more expensive than nickel plating; but, subject to the plating being done really well, it is far more durable, and very advantageous from the point of view of labour-saving. There is no necessity to use any patent polish; and, in fact, if such polish is used, it destroys the chromium. It is also found that the plating is more durable on metals other than steel. The use of chromium plating for articles other than motor cars is becoming wider every day; and, in fact, at present there is nothing which can compare with it for durability and efficiency, except stainless steel, which, though more expensive, is everlasting. Stainless steel is not, however, at present obtainable for many articles and purposes.

Income Tax

Accident Insurance Benefit

"C. C. M." has been receiving disablement benefit for some weeks in respect of a fractured ankle, and during that time has had to incur special expenses—locumtenent, chauffeur, masseuse, etc. What is the position as regards the benefit received and the expenses?

*** The benefit is not income assessable to income tax, and should not be included in his gross professional receipts. The expenses are deductible in so far as they are incurred in carrying on his practice, but not otherwise—for example, the cost of the locumtenent and chauffeur would be deductible, but not the expense of any treatment of himself, such as the cost of the services of a masseuse.

Cash Basis

A and B were in partnership for twenty years, during which time they were assessed on the basis of their gross receipts. B died, and C entered into partnership with A. The inspector now claims that the total earnings of B and C, including outstanding book debts, should be brought into the computation.

*** Unless A and C and B's executors join in requiring the assessments to be treated on the footing that the old practice ceased at B's death and was restarted anew when C joined, the liability, so far as gross receipts are concerned, falls to be calculated on the usual basis of the previous year, in which case we see no reason why the cash basis should not be continued, provided that the receipts brought into the calculation include amounts paid over to B's executors. On the other hand, if the practice is being treated as having been stopped and restarted, the cash receipt basis is not applicable, because the first year's receipts would not fully represent the gross earnings of the practice, and the value (not necessarily the nominal amount) of the outstanding debts should be brought into the figures.

Remuneration of Daughter as Locumtenent

"R. W." inquires whether he can charge as an expense the rent of a house which is occupied by his daughter, who acts as an occasional locumtenent for him; and, if so, whether she would have to return this £70 (rental value) as part of her income.

*** It is to be assumed that the revenue authorities may look somewhat carefully at such financial arrangements between parent and daughter, as they may be personal rather than, or at any rate as well as, on a professional footing. If, however, as we gather is the case, "R. W." can show that the total amount charged in respect of his daughter's professional services, including the £70, bears a reasonable relation to what would be paid to a stranger on a *quantum meruit* basis, we think he can enforce his claim by appeal, if necessary. As regards the daughter's liability, if she, or her husband, has the usual rights of a tenant, including power to sublet, we consider she is bound to bring the £70 in as part of their joint incomes, though probably not as remuneration assessable under Schedule E or Schedule D, but, as a free occupier, under Schedule A.

Holidays: Domestic Expenses

"HOLIDAYS" points out that if he were not in practice he would shut up his house during holidays "and send the maids home, only paying their wages." Instead, he has to employ a housekeeper, and keep the house running as usual for the accommodation of a locumtenent. Can such expenses be deducted for income tax purposes?

*** The question is not easy to answer definitely. The statutory rules provide that "expenses, not being money wholly and exclusively laid out for the purpose of the profession" shall not be deducted, and the expense of keeping a house aired, cleaned, and in running order has a semi-personal side to it, which makes the insertion of the word "exclusively" in the rule difficult to deal with. At the same time any special expenses incurred in connexion with the locumtenent, such as the employment of the housekeeper and the expenses relevant to his accommodation,

the provision of his board and domestic service, can properly be taken into account when estimating what is the appropriate fraction of the total domestic expenses to be taken into account for the year in question as the professional rather than the domestic cost of the whole.

Motor Car Allowance

"M. J. C." bought an "X" car in 1929 for £135 and was allowed £27 depreciation thereon as for 1930-31. In November, 1930, he sold the car for £45 and bought a "Y" car for £110. What should he claim in the accounts which he is sending in for the 1931-32 assessment?

*** (1) Obsolescence allowance—that is, £135 - £27 - £45 = £63—as a professional expense of the year 1930, and (2) depreciation allowance for 1931-32 at 20 per cent. of £110 = £22.

LETTERS, NOTES, ETC.

Sodium Nucleinate in Pneumonia

Dr. H. J. CLUTTERBUCK (Llanelly) writes: Some years ago a medical man, in the course of a discussion in the *Journal* on the treatment of acute lobar pneumonia, said that he had been "crying in the wilderness" for some time the value of sodium nucleinate injections (0.1 gram in 2 c.c.m.). I thereupon decided to try the method, and have been astonished at the results, if given early. The following case has just occurred in our practice. Dr. Gordon Bennett saw a road-worker, aged 40, on March 27th, at about 6 p.m. He had then been working until tea-time, when he had a rigor. His temperature was 104° F., and his respirations 60, with pulse 120, and severe pain in the right chest, especially the subclavicular region. He was put on antiphlogistine and glucose, with an expectorant mixture. I saw him in the afternoon of the 28th, when there was definitely pneumonic sputum. I gave him one injection of sodium nucleinate subcutaneously in his forearm. This produced violent perspiration, and he was bathed with tepid water. Next morning his temperature was normal, pulse rate 75, and respiration normal. He said that he felt much better; no pain, and the cough much easier, although his sputum continued to be blood-stained, but not so much as before. On the 30th, at 10 a.m., the temperature was still normal and the patient going on well. At 7.30 p.m., after calomel overnight and saline in the morning, he had had a good result, and was demanding food. Both Dr. Gordon Bennett and myself were so astonished at the transformation in his condition, less than thirty-six hours after the infection, that we consider it our duty to notify the facts. This is not the first time by any means that I have got a good result with the sodium nucleinate, but such a marvellous change in this man's condition after its use has induced us to recommend its trial early in cases of acute lobar pneumonia.

Migration and Health

Dr. J. S. PURDY, Metropolitan M.O.H., Sydney, N.S.W., sends the following addendum to the letter published on January 3rd (p. 36), in which he substituted "sixth" for "fourth" in his earlier statement "There is no one living in Australia (other than the Aborigines) who is a descendant of the fourth generation of Australians": I quoted the grandchildren of Dr. Antill Pockley as of the fifth generation, and a great-grandson of Mrs. Brennan of Darlington, Sydney, whose grandmother was born in Liverpool, New South Wales. Dr. J. R. Nimmo of Brisbane now writes to me: "My maternal grandmother was born at Government House during her father's governorship (P. G. King). He left for England in 1805, having come out with the First Fleet in 1788. My grandfather was born at Penrith, my mother at Rosedale, Victoria, my eldest sister at sea in Cooktown Harbour, and her eldest child, now 15 years old, at Atherton, North Queensland. This makes five generations Australian born, and there are at least thirty-two of this generation who are descendants of my grandfather alone. Governor King spent seventeen years in Norfolk Island and Sydney, but of course cannot be claimed as a native (if he is included it brings the figure to six). Three of his four children married and settled in Australia; of the three, two were English born (Admiral P. P. King and Mrs. Hannibal MacArthur), the other and youngest, Mary, became the wife of R. C. Lethbridge, and is the first generation of our maternal stock in this country." These details are interesting, as they concern descendants of one of the first white men to step ashore at Port Jackson on January 26th. As it is only 143 years since the arrival of the First Fleet and the founding of the Settlement by Governor Phillip, although there is no one living in Australia (other than Aborigines) who is a descendant of the sixth generation of Australians, it is of interest to know of cases of the fifth generation, especially of descendants of our third governor, P. G. King.

Clinical Thermometers

Dr. A. STEWART ROBERTSON (Weston-super-Mare) writes: I think practitioners should be warned to be careful in the use of the cheap thermometers which are now on the market. We bought a number of these in March at 1s. 4d. each. Having reason to suspect the accuracy of one I was using, I tested fourteen of them simultaneously in warm water at two different temperatures, and for two different periods of time—two minutes and one minute respectively. The thermometers themselves are all marked "1/2 minute," and each carries the following certificate of guarantee:

> "This is to certify that the clinical thermometer enclosed herewith has been compared with our standard (corrected by the Government National Physical Laboratory, Teddington, England), and found correct within 0.2° F. Also that the bulb is made of 'normal glass,' which makes the thermometer unalterable for all time."

The readings obtained were as follows:

2 minutes immersion.	1 minute immersion.
108·8	103·6
108·8	104·4
108·4	103
108·6	103·2
108·8	103·4
109	104·2
109·4	103·6
110	105
108·6	103·4
109·8	105·4
109	104
108	104·4
109	105·4
109·6	104·2

Pregnancy Records

Dr. F. H. WATSON (Bowral, N.S.W., Australia) writes: In the *British Medical Journal* of December 20th, 1930, "J. J. S." reports a "record pregnancy." The following case breaks his record by two days. On January 14th, 1929, at 11.30 p.m., Mrs. D., 5-para, gave birth to a female child, and on November 23rd, 1929, at 9 p.m., was delivered of a full-time male infant.

Corrigendum

WE are requested to state that in an announcement in our *last issue* the title of Professor Samson Wright's Oliver-Sharpey Lectures at the Royal College of Physicians should have read: "Certain aspects of the reflex control of the *circulation*."

First-aid Outfits for Motorists

IN anticipation of Safety Week (May 11th to 16th) the British Red Cross Society is putting *on the market* a number of first-aid outfits for motorists. These are to be available in three sizes (10s. 6d., 28s. 6d., and 42s.). The first is intended for *private cars*; the other two are designed to meet the road accident needs of motor coaches. In addition, the society has prepared a "field dressing" at 1s. These *Red Cross outfits* are made up in strong black tin boxes, decorated with the official emblem, and everything in them is of British manufacture.

The Automobile Association's map showing parking places in Central London has recently been revised and brought up to date. It shows the location of over fifty parking places, specifies the maximum period of continuous waiting, and also the particular *hours during* which cars may be parked. Additional information is given of ninety parking places in the outer London traffic area. Copies of the map may be obtained free by members from the A.A., Fanum House, New Coventry Street, W.1, or from any branch office.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 58, 59, and 60 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 56 and 57.

A short summary of vacant posts notified in the advertisement columns appears at page 831.

VACANCIES

ABERDEEN ROYAL INFIRMARY.—Hon. M.O. in Charge of Department for Diseases of the Skin.

BARROW-IN-FURNESS COUNTY BOROUGH.—Assistant M.O. (woman).

BELGRAVE HOSPITAL FOR CHILDREN, Clapham Road, S.W.9.—H.S.

BIRMINGHAM CITY.—Junior R.M.O., Maternity and Child Welfare Department.

BIRMINGHAM: GENERAL DISPENSARY.—Resident Locumtenent M.O. (male).

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—H.S.

BIRMINGHAM: QUEEN'S HOSPITAL.—Hon. Ophthalmic S.

BIRMINGHAM UNIVERSITY.—Professor of Anatomy.

BLACKBURN: ROYAL INFIRMARY.—Fourth H.S. (male).

BOOTLE GENERAL HOSPITAL.—Two H.S.

BRIGHTON, HOVE, AND PRESTON DISPENSARY AND HOVE HOSPITAL.—Hon. P. at Ditchling Road Dispensary.

BRIGHTON: NEW SUSSEX HOSPITAL FOR WOMEN.—(1) H.P. (2) H.S. (3) Hon. Assistant Ophthalmic S.

CANCER HOSPITAL, Fulham Road, S.W.3.—Director of Research Institute.

CHEADLE ROYAL MENTAL HOSPITAL.—Locumtenent.

CHESTERFIELD AND NORTH DERBYSHIRE ROYAL HOSPITAL.—(1) C.O. (2) H.S.

COLNE BOROUGH.—M.O.H.

CONNAUGHT HOSPITAL, Orford Road, E.17.—R.C.O. (male).

COSSHAM MEMORIAL HOSPITAL, Kingswood.—H.S.

DERBYSHIRE ROYAL INFIRMARY.—C.O.

DONCASTER ROYAL INFIRMARY.—H.S. (male).

DOVER CORPORATION.—Assistant M.O.H.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—R.M.O.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.1.—R.C.O. (male).

EAST SUSSEX COUNTY MENTAL HOSPITAL, Hellingly.—Two J.A.R.M.O.'s (males, unmarried).

ELIZABETH GARRETT ANDERSON HOSPITAL, Euston Road, N.W.1.—(1) H.P. (2) Obstetric Assistant. (3) Three H.S. Women.

GREENOCK CORPORATION.—Locumtenent for Public Health Department.

GREENOCK ROYAL INFIRMARY.—H.S. (lady).

HONG-KONG UNIVERSITY.—Professor of Pathology.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.—Two Medical Registrars.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Ophthalmic S. (male).

HOVE, LADY CHICHESTER HOSPITAL.—(1) H.P. (woman). (2) Junior.

HUDDERSFIELD ROYAL INFIRMARY.—H.S. (male).

HULL: CITY AND COUNTY OF KINGSTON-UPON-HULL.—J.R.M.O. (woman) at Maternity Home and Infants Hospital.

HULL ROYAL INFIRMARY.—H.S. (male) to Ophthalmic and Ear, Nose, and Throat Departments.

HULL: VICTORIA HOSPITAL FOR SICK CHILDREN.—(1) R.H.S. (2) R.H.P. Ladies.

ILFORD BOROUGH.—Assistant M.O.H.

ILFORD ISOLATION HOSPITAL.—Temporary R.M.O. (lady).

ILFORD: KING GEORGE HOSPITAL.—Two H.S. (males).

LEEDS HEBDEN MOSLEY HOSPITAL.—R.M.O.

LEICESTERSHIRE AND RUTLAND MENTAL HOSPITAL.—A.M.O. (male, unmarried).

LIVERPOOL HAHNEMANN HOSPITAL.—Clinical Assistant to Ophthalmological Department.

LIVERPOOL MATERNITY HOSPITAL.—H.S.

LONDON HOSPITAL, E.—A.P. to Children's Department.

LONDON JEWISH HOSPITAL, Stepney Green.—(1) Registrars, (*a*) Medical, (*b*) Surgical, (*c*) Ear, Nose, and Throat. (2) R.M.O. (3) J.R.M.O. (4) C.O.

MACCLESFIELD GENERAL INFIRMARY.—Second H.S.

MANCHESTER ANCOATS HOSPITAL.—H.S. (Orthopaedic).

MANCHESTER BABIES' HOSPITAL.—Hon. Anaesthetist.

MANCHESTER EAR HOSPITAL.—Non-resident H.S.

MANCHESTER ROYAL INFIRMARY.—H.S. (lady) at Central Branch.

MANSFIELD AND DISTRICT HOSPITAL.—H.S. and C.O. (male).

MIDDLESBROUGH NORTH ORMESBY HOSPITAL.—H.S. (male, unmarried).

MUSGRAVE HOSPITAL, W.1.—Assistant in the Department of Radium Therapy and Research.

MUKDEN MEDICAL COLLEGE, Manchuria.—Pathologist.

NEWCASTLE-UPON-TYNE: HOSPITAL FOR SICK CHILDREN.—H.S.

NEWPORT, MON.: ROYAL GWENT HOSPITAL.—J.R.M.O.

NORFOLK AND NORWICH HOSPITAL.—C.O. and H.S. (male).

NORTHUMBERLAND MENTAL HOSPITAL, Morpeth.—Locumtenent.

NOTTINGHAMSHIRE COUNTY COUNCIL.—Assistant M.O. for Maternity and Child Welfare (woman).

OLDHAM ROYAL INFIRMARY.—H.P. and C.O.

OXFORD EYE HOSPITAL.—H.S.

OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—R.M.O. at Osler Pavilion.

PLYMOUTH: CENTRAL HOSPITAL.—H.S.

PONTEFRACT GENERAL INFIRMARY.—R.M.O.

POPLAR HOSPITAL FOR ACCIDENTS, E.14.—Senior Resident Officer.

QUARRIER'S HOMES AND BRIDGE OF WEIR SANATORIUM.—Resident Female M.O.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—(1) H.S. (male). (2) C.O. (3) H.P.

READING: ROYAL BERKSHIRE HOSPITAL.—(1) C.O. (2) Resident Anaesthetist. Males.

ROTHERHAM HOSPITAL.—(1) C.H.S. (2) H.P. Males.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—(1) Examiner. (2) Hunterian Professor. (3) Arris and Gale Lecturer. (4) Erasmus Wilson Lecturer.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.—(1) A.M.O. in V.D. Department (female). (2) Senior Clinical Assistant in the Children's Department.

RUGBY: HOSPITAL OF ST. CROSS.—Three R.M.O. (males).

ST. ALBANS AND MID-HERTS HOSPITAL.—R.H.S. (female).

ST. MARY'S HOSPITAL, Paddington, W.2.—(1) Second Obstetric S. in Charge of Out-patients. (2) Resident Anaesthetist.

ST. THOMAS'S HOSPITAL, S.E.1.—Visiting Anaesthetist.

SALVATION ARMY.—Assistant R.M.O. (woman) for the Mothers' Hospital.

SOUTHEND VICTORIA HOSPITAL.—J.H.S. (male).

STOKE-ON-TRENT: NORTH STAFFORDSHIRE ROYAL INFIRMARY.—H.S.

SUNDERLAND: ROYAL INFIRMARY.—H.P. (male).

TRURO: ROYAL CORNWALL INFIRMARY.—H.S. (male).

WALSALL GENERAL HOSPITAL.—H.S.

WESTERN OPHTHALMIC HOSPITAL, Marylebone Road, N.W.1.—Junior Non-resident H.S.

WORCESTER GENERAL INFIRMARY.—J.H.S.

CERTIFYING FACTORY SURGEONS.—The appointments at Tooting (London) and Cromarty (Ross and Cromarty) are vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1.

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT for the Bedford, Hitchin, Luton, Biggleswade, Huntingdon, Peterborough, Thrapston, and Oundle County Courts. Applications to the Private Secretary, Home Office, Whitehall, S.W.1, by May 27th.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

APPOINTMENTS

McCAY, F. H., M.B., B.Chir.Cantab., Resident Medical Officer at the Presidency General Hospital, Calcutta.

CERTIFYING FACTORY SURGEONS.—S. F. Fouracre, M.B., B.S.Lond., for the Withernsea District, York; J. Franks, M.R.C.S., L.R.C.P., for the Winchester District, Southampton; A. Macphail, M.B., Ch.B., for the Stornoway District, Ross and Cromarty; L. B. Maxwell, M.B., B.Ch.Camb., for the Sutton District, Surrey; L. E. Owen, M.R.C.S., L.R.C.P., for the Clynderwen District, Pembroke.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.1.—*Hunterian Lectures* by Sir Arthur Keith: Mon. and Wed., 5 p.m., and Fri., 4 p.m., Human Monsters and Malformations.

ROYAL SOCIETY OF MEDICINE

Section of Psychiatry.—Tues., 8.30 p.m., Annual General Meeting. Paper, Dr. Emanuel Miller: Eiditic Image as an Undertone of Psychosis.

Section of Surgery: Subsection of Proctology.—Wed., 5 p.m., Annual General Meeting. Discussion: The Injection Treatment of Piles. The annual dinner will be held at the Langham Hotel at 8.15 p.m.

Section of Neurology.—Thurs., 8.30 p.m., Annual General Meeting. Specimens.

Section of Obstetrics and Gynaecology.—Fri., 8 p.m., Annual General Meeting. Discussion: The Relative Value of the Induction of Premature Labour, Test Labour, and Caesarean Section in the Treatment of Minor Degrees of Contracted Pelvis. Openers, Mr. R. Alan Brews, Mr. G. F. Gibberd, Dr. J. W. A. Hunter (Manchester), Dr. A. Morris-Jones, Dr. Margaret Salmond, Dr. J. Gardener Wigley, and Dr. A. J. Wrigley.

CHADWICK PUBLIC LECTURE at Institute of Mechanical Engineers, Storey's Gate, Westminster, S.W., Fri., 8 p.m. Professor E. L. Collis: The Coal Miner, his Health and Occupational Diseases.

HARVEIAN SOCIETY, Town Hall, Paddington, W.—Thurs., 8.30 p.m., Discussion: Indication and Method of Treatment in Calcium Therapy. To be opened by Dr. Donald Hunter.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—*Mon.*, 8 p.m., Annual General Meeting. 9 p.m., Annual Oration on Medicine as a Science and an Art, by Sir John Rose Bradford, Bt., followed by a conversazione.

PADDINGTON MEDICAL SOCIETY, Great Western Royal Hotel, Paddington.—Tues., 9 p.m., Address by Dr. E. C. Morland (assistant editor of the *Lancet*): Medical Journalism.

BIRMINGHAM UNIVERSITY.—Wed., 4 p.m., Sir Hubert Bond: Some Correlations between General and Psychological Medicine.

POST-GRADUATE COURSES AND LECTURES

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—At *Medical Society of London*, 11, Chandos Street, W.1: M.R.C.P. Special Evening Lectures: Tues., 8.30 p.m., Dr. Donald Hunter, Bone Growth and Metabolism—Medical Aspects of Diseases of Bones; Fri., 8.30 p.m., Dr. L. J. Witts, Achlorhydria and Anaemia; tickets, 10s. 6d. each lecture, may be taken at the lecture hall. *British Red Cross Rheumatism Clinic*, Pete Place, Regent's Park: Mon., 2 p.m., Dr. B. S. Nisse, Demonstration in Women's Out-patient Department; no tickets necessary. *St Mark's Hospital*, City Road, E.C.: Tues., 5 p.m., Demonstration in Out-patient Department by Mr. W. B. Gabriel; no tickets required. *Prince of Wales's Hospital*, Tottenham, N.15: Special all-day Post-Graduate Course in General Medicine, Surgery, and the Special Departments; Demonstrations, Operations, Lectures; tickets from the Fellowship of Medicine. *City of London Hospital for Diseases of the Heart and Lungs*, Victoria Park, E.: All-day Post-Graduate Course in Diseases of the Chest; Lectures and Demonstrations; tickets from the Fellowship of Medicine. *Royal Eye Hospital*, Southwark, S.E.1: Afternoon Course in Ophthalmology, Demonstrations daily at 3 p.m.; tickets from the Fellowship of Medicine. *St. John's Hospital*, Leicester Square, W.C.: Afternoon and Evening Demonstrations in Skin Diseases; tickets from the Fellowship of Medicine. Copies of all Syllabuses from the Fellowship of Medicine, 1, Wimpole Street, W.1.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.1.—*Daily*, Intensive Course.

CITY OF LONDON MATERNITY HOSPITAL, City Road, E.C.1.—Thurs., 5 p.m., Dr. H. Burt-White, Diagnosis and Treatment of Uterine Infection.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.2.—Mon., 5 p.m., Dr. H. MacCormac, Treatment of Syphilis. Tues., 5 p.m., Dr. W. N. Goldsmith, The Nervous System in Relation to Skin Diseases. Thurs., 5 p.m., Dr. J. M. H. MacLeod, Infections of the Skin with Yeast-like Organisms. Fri., 5 p.m., Dr. W. Knowsley Sibley, Alopecia.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Keppel Street, W.C.1.—Mon., 5 p.m., Dr. C. F. White, Port Work. Wed., 5 p.m., Dr. Bernard Hart, Mental Hygiene. Fri., 5 p.m., Professor E. L. Collis, Industrial Hygiene—Respiratory Diseases.

NATIONAL HOSPITAL, Queen Square, W.C.1.—Mon. to Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Dr. Greenfield, The Cerebro-spinal Fluid; 3.30 p.m., Mr. W. Noble, Defects in the Visual Fields. Tues., 3.30 p.m., Mr. Armour, Head Injuries. Thurs., 3.30 p.m., Dr. Critchley, Cerebral Vascular Disease. Fri., 3.30 p.m., Mr. Elmquist, Demonstration of Reeducative Exercises.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.—Mon., 2.30 to 5 p.m., Medical, Surgical, and Gynaecological Clinics, Operations. Tues., 2.30 to 5 p.m., Medical, Surgical, and Throat . . . . 2.30 to 5 p.m., Medical, Skin, and Thurs., 11.30 a.m., Medical, Surgical, Throat, and Children's Clinics, Operations. Fri., 10.30 a.m., Throat Clinics; 2.30 to 5 p.m., Medical and Surgical Clinics, Operations.

ST. PAUL'S HOSPITAL FOR GENITO-URINARY DISEASES, Endell Street, W.C.2.—Wed., 4.30 p.m., Mr. H. P. Winsbury White, Modern Methods of Diagnosis in the Upper Urinary Tract (Lantern Demonstration).

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley Road, Balham, S.W.—Wed., 4 p.m., Dr. H. Crichton-Miller, Functional Neurosis in General Practice.

BIRMINGHAM UNIVERSITY CLINICAL BOARD.—At General Hospital: Tues., 3.30 p.m., Mr. B. T. Rose, Common Disorders of the Rectum and Anus. At Queen's Hospital: Fri., 3.30 p.m., Dr. P. Cloake, Demonstration of Medical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Western Infirmary: Wed., 4.15 p.m., Dr. J. R. Riddell and Dr. S. D. Scott Park, Radiation Therapy.

LIVERPOOL UNIVERSITY CLINICAL SCHOOL ANTE-NATAL CLINICS.—Royal Infirmary: Mon. and Thurs., 10.30 a.m. Maternity Hospital: Mon., Tues., Wed., Thurs., and Fri., 11.30 a.m.

MANCHESTER ROYAL INFIRMARY.—Tues., 4.15 p.m., Dr. T. H. Oliver, Rheumatoid Arthritis. Fri., 4.15 p.m., Mr. A. H. Burgess, Demonstration of Surgical Cases.

MANCHESTER VICTORIA MEMORIAL JEWISH HOSPITAL.—Wed., 4.30 p.m., Dr. H. Morris, Demonstration of Cases in the X-ray Department.

MEDICAL SECRETARY (Telegrams: Mediscera Westcent, London).

EDITOR, BRITISH MEDICAL JOURNAL (Telegrams: Aitiology Westcent, London).

Telephone numbers of British Medical Association and British Medical Journal, Museum 9861, 9862, 9863, and 9864 (internal exchange, four lines).

SCOTTISH MEDICAL SECRETARY: 7, Drumsheugh Gardens, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 24361 *Edinburgh*).

IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin. (Telegrams: Bacillus, Dublin. Tel.: 4737 Dublin.)

Diary of the Association

MAY

8 Fri. London: Public Health Committee, 2.30 p.m.

10 Sun. West Suffolk Division: West Suffolk Hospital, Bury St. Edmunds, 11 a.m. Sir Thomas Horder's Clinic.

12 Tues. Barnet Division: Cottage Hospital, Barnet, 4 p.m. Business Meeting.
St. Pancras Division: B.M.A. House, Tavistock Square, 9 p.m. Annual General Meeting.

13 Wed. Portsmouth Division: Queen's Hotel, Southsea, 7.45 p.m. Annual Dinner.
Southampton Division: Stoneham Golf Course. Bogey Competition for Divisional Stage of Treasurer's Cup Golf Competition.

14 Thurs. London: Journal Committee, 2.30 p.m.
Cleveland Division: Zetland Hotel, Saltburn, 3 p.m. *Annual Meeting.*
Hampstead Division: Hampstead General Hospital, 8.30 p.m.
West Suffolk Division: Worlington. Annual Golf Competition.

15 Fri. Bedfordshire Division: Bedford County Hospital, 3 p.m. General Meeting.
City Division: Metropolitan Hospital, Kingsland Road, E., 4.15 p.m. Clinical Meeting.

19 Tues. City Division: Metropolitan Hospital, Kingsland Road, E., 9.30 p.m. General Business Meeting.
Derby Division: Board Room, Derbyshire Royal Infirmary, 3.30 p.m. General Meeting.

20 Wed. London: Finance Committee, 2.30 p.m.
Willesden Division: Willesden General Hospital, 9 p.m. Annual Meeting.

21 Thurs. London: Charities Committee, 2.30 p.m.

28 Thurs. London: Insurance Acts Committee, Rural Practitioners' Subcommittee, 2.30 p.m.
West Norfolk Division: Globe Hotel, King's Lynn, 7.30 for 8 p.m. Annual Dinner. Address by Dr. T. H. Pear.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTHS

ELDER.—On April 30th, 1931, at 27, Welbeck Street, W.1, to Marjorie, wife of Howard H. A. Elder, M.B., Ch.B., 225, Portland Road, South Norwood, S.E.25, a son.

GALLAGHER.—On May 1st, 1931, at Talfourd House, Mount Pleasant Road, Hastings, to Dorothy (née Hammick), wife of Dr. Charles E. Gallagher, a son.

MARRIAGE

GRAHAM—MACLEOD.—On April 15th, 1931, at Lybster, by the Rev. R. Wilson, M.A., Frank Ogle Graham, M.B., Ch.B., son of Alderman and Mrs. J. T. Graham of Hartlepool, to Annie Campbell Mackay MacLeod, M.A., only daughter of Mr. and Mrs. J. R. MacLeod of Lybster, Caithness.

DEATHS

GODWIN.—On April 28th, 1931, at Hampstead, Dr. W. H. Fenn Godwin, Captain R.A.M.C. (ret.), only surviving son of the late Captain John Godwin, R.E., Military Knight of Windsor.

GRIFFITHS.—On May 1st, at his residence, Ynyslas, Picton Avenue, Porthcawl, Glam., Evan John Griffiths, M.B., Ch.B.Ed., *D.P.H.*, the dearly loved husband of Bet Griffiths, and late M.O.H. for Pontypridd.

KAY.—On April 22nd, 1931, suddenly, *in London*, Walter Smith Kay, M.D., of Harrogate, late Medical Superintendent of West Riding Mental Hospital, Wadsley, Sheffield.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

435 Cardiac Disease and Urinary Retention

S. G. STEWART (*Amer. Journ. Med. Sci.*, March, 1931, p. 362) discusses the relations between chronic bladder obstruction and disease of the heart, reviewing the results obtained from bladder drainage in a series of 40 prostatic patients with cardiac symptoms. Decompensation occurred in 12; all except 3 of these were greatly improved by prostatectomy, compensation being restored and maintained without the aid of digitalis. In 3 out of 5 cases of auricular fibrillation the rhythm became regular again after bladder drainage, and has remained so. Partial heart-block was present in two cases; the conduction time became normal in one after bladder drainage, and in the other after prostatectomy. Digitalis was not used in either instance. Extrasystoles were numerous in 15 cases, but disappeared completely with bladder drainage in all except one. Stewart remarks that, since in 22 out of the 40 cases in this series cardiac arrhythmias developed, and were corrected in all but 3 by the relief of the urinary obstruction, there must be a definite relation between bladder retention and the functioning of the heart. Arterio-sclerosis was an outstanding feature in this series, occurring in 28 cases, retinal arterio-sclerosis being prominent in 24. Advanced coronary sclerosis was found in 4 out of 5 necropsy cases, and moderate sclerosis in the fifth. The average age of these patients was 67, and the systolic blood pressure never rose above 160. The author insists on the need for adequate urological histories being obtained when dealing with male cardiac patients past middle life. He discusses the risk of catheter infection, maintaining that no serious complications need be expected necessarily from the use of the permanent catheter, although the coexistence of oedema and diabetes constitutes a real danger signal.

436 The Negative Phase in Immunity to Diphtheria

R. PRIGGE (*Med. Klinik*, March 20th, 1931, p. 419) records his experiments on guinea-pigs to determine the presence of a negative phase after active immunization against diphtheria, and comes to the following conclusions. (1) Guinea-pigs with formolized vaccines against diphtheria toxin or diphtheria bacilli do not show an increased susceptibility to diphtheria toxin, or increased liability to be infected by diphtheria bacilli, provided the dose of vaccine has not been too high. (2) An increased susceptibility is produced only by a considerable overdosage of vaccine. It is not yet decided whether this should be regarded as a negative phase in the ordinary sense of the term, or as damage due to excessive dosage. (3) In the active immunization of human beings the dose of vaccine is 100 to 200 times smaller than that used in experimental work on animals without causing any hypersensitiveness. It can therefore be concluded with a probability bordering on certainty that the occurrence of a negative phase can be excluded in the active immunization of human beings against diphtheria.

437 Essential or Familial Haemophilia

P. CHEVALLIER and R. GOLDBERG (*Rev. de Méd.*, February, 1931, p. 126) preface a study of essential haemophilia with descriptions of its anthropological characters, its various predispositions, and its pathology. In this disease, which is confined principally to males, the subject is apparently in perfect health; a haemophilic facies does not exist. There are two types of haemorrhage, external and internal, or the haematoma. Large haematomas tinge the skin yellow and are accompanied by urobilinuria; the haemorrhages heal as in normal persons. The haemophilic bleeds easily, often, and at any organ, though the bleeding is almost always localized to a single site; the haemorrhages are often provoked by the slightest cause. Retarded coagulation of the blood is a characteristic phenomenon; no other haemic changes occur, and all the signs of purpura haemorrhagica are absent. Vascular fragility, chiefly of the arterioles, is present. Haemophilia is always manifested in early life; in 75 per cent. of cases the first bleeding occurred before the age of 2 and never after 22. Though not progressive, the disease is incurable, and death is often an early sequel; consequently, the prognosis is always grave. Various local cutaneous and muscular manifestations are described by the authors, and the differential diagnosis is discussed. Treatment is unsatisfactory; it comprises eugenic precautions, cure of the diathesis, and treatment of the haemorrhages. Many methods have been employed to establish diathetic cure: hygienic and dietetic measures; vegetable and animal extracts; and various drugs, such as calcium chloride and peptone. Treatment of the haemorrhages is general and local. The former includes the injection of serum or of whole blood, of emetine, and of pituitary extract. Compresses soaked in serum and ice are good local measures. Haematomas should be incised and filled with some coagulant. Cauterization is contraindicated, since the subsequent separation of the scar might prove dangerous.

438 Hypochromic Anaemia with Achlorhydria

T. R. WAUGH (*Arch. Int. Med.*, January, 1931, p. 71) describes cases of anaemia which he regards as a special disease entity quite distinct from chlorosis or pernicious anaemia, and without association with the anaemia of haemorrhage. The chief feature is hypochromia; the red cells are moderately reduced in number to 3.5 or 4 millions per c.mm., but the haemoglobin is diminished by 30 to 60 per cent., and there is consequently a low colour index. These changes are associated with hypochlorhydria or even complete absence of free hydrochloric acid after a test meal. All the patients were women of 35 to 45 years of age, and no case occurred after the menopause. The clinical symptoms were not severe and were not relieved by liver diet; treatment with iron or arsenic gave doubtful results, and any benefit from transfusion was only temporary. The condition is very chronic, lasting over a period of years, but no fatal cases are reported.

439 Etiology of Chorea

ANDRÉ-THOMAS (*Presse Méd.*, March 4th, 1931, p. 337) reports a case in which spontaneous jerky actions supervened in the left half of the body, except in the muscles of the face, neck, and trunk, after a sharp attack of left hemiplegia, and after the power of movement had clearly been restored. These movements resembled in many respects the motor agitation manifested in young choreics. For various reasons the author classifies this case as one of post-hemiplegic chorea, and discusses the pathology of that disease. Lesions in many cerebral centres have been advanced as the origin of choreic movements; these are enumerated. Monakow has concluded, from the diversity in the sites of the lesions and their symptomatology, that hemichorea assumes very different aspects, corresponding to the various areas affected. André-Thomas believes that the cerebral cortex plays a part in the production of choreic movements. This lesion is not the sole factor to be considered in the pathology of the disease. Many other contingencies intervene, among which are psycho-emotive variations, and endocrine and humoral disturbances. Clinical and anatomical studies of chorea, and of the conditions which provoke the appearance of choreic movements, demonstrate an abnormal sensitivity of the cortical centres governing such acts. This enhanced sensitivity is not peculiar to chorea, but can develop in various affections of the centres, it varies in form and localization with the nature and site of the

initial lesion. The cortex need not be directly involved by the lesion; the symptoms can be the result of a lesion more or less removed from the centres apparently implicated.

440 Gastric Syphilis simulating Carcinoma

G. BELL and A. H. TEBBUTT (*Med. Journ. Australia*, January 17th, 1931, p. 81) report the case of a naval stoker, aged 37, who complained of dull aching pain over the epigastrium, and sickness soon after food. The duration of the illness was six months, and there was no history of venereal disease. He had lost 2 stone in weight, and his bowels were constipated and irregular. There was tenderness over the pyloric area but no palpable mass. An *x*-ray examination revealed a subtotal pyloric obstruction and a large filling defect of the pylorus, which suggested malignant disease. A fractional test meal showed a fasting residue consisting of 200 c.cm. of bile-stained fluid with much muco-pus and no acid. Occult blood was present. After a test breakfast there was neither hydrochloric nor lactic acid. The stomach did not empty in three hours. Malignant disease of the pyloric end of the stomach was diagnosed, but the Wassermann test gave a strongly positive reaction. The patient was given intensive antisyphilitic treatment for three weeks, and was then submitted to laparotomy. The pyloric end of the stomach was found to be infiltrated and thickened; it was resected and a gastro-enterostomy was performed. Recovery was uneventful. Naked-eye and microscopical examination showed erosion of the mucosa not involving the muscularis. There was marked infiltration of the submucosa by round cells, plasma cells, endothelial cells, and eosinophils. In the muscularis and the submucosa were found giant-cell systems typical of tuberculosis. Marked obliterative endarteritis was found in several vessels.

441 Deafness in Trichinosis

H. BOSCH (*Münch. med. Woch.*, March 13th, 1931, p. 431) records the case of a woman, aged 51, in whom an attack of trichinosis was complicated by deafness in both ears. Otitis media could be excluded, and Bosch comes to the conclusion that the condition is similar to that met with in other infectious diseases, such as typhoid fever, mumps, malaria, influenza, scarlet fever, and diphtheria, in which toxic neuritis occurs. The condition was not due to direct damage to the auditory apparatus by trichinellae, or to any therapeutic cause, since only indifferent drugs were used.

Surgery

442 Treatment of Varicose Veins

C. P. LOPEZ (*Bull. et Mém. Soc. Chir. de Paris*, February 6th, 1931, p. 57) enumerates the various solutions which may be injected for the treatment of varicose veins; he points out that the ideal injection must be sterile, and it must be performed with sufficient pressure to fill even the smallest varicose vessel. In addition, it must produce thrombosis and sclerosis of the veins, and must be antiseptic to obviate any risk of suppuration in the venous thrombus. Ether, it is stated, fulfils all these conditions. At a temperature of about 35° C. it becomes a gas, and exerts enough pressure to penetrate the varicose venous system completely. A tight tourniquet placed at the top of the limb undergoing treatment prevents the ether from entering the general circulation. Within an hour after the injection the ether is absorbed, and has so completely disappeared that it is possible to remove the tourniquet. After the injection the veins become turgid as if they were going to burst, and pressure with the finger gives the sensation of gas in the veins. After fifty or sixty minutes the swelling disappears, while the veins become hard. The patient must remain in bed for four to eight days following the injection. Sometimes at different points in the vein extravasations of blood appear; these are later detached as small scabs, which may leave a scar. At first the varicose vein will have the appearance of a cord, which is hard to the touch but not painful, but at the end of several months the vein shrinks, and gradually disappears. One hour before the ether is injected an injection of 1 cg. of morphine is given. As a general rule two injections of 1 to 1½ c.cm. of ether are found to be sufficient, although a third may be given if necessary. Twenty-two cases have been treated by this method, but no end-results or clinical observations are given.

443 As a radical cure for varices, H. JAUSION, E. CARROT, and A. GERVAIS (*Bull. Soc. Franç. de Derm. et de Syph.*, February, 1931, p. 171) recommend intravenous injections of glycerin diluted to one-third. While the excessive viscosity of too concentrated solutions should be avoided, yet a sufficient strength must be used. The authors recommend a mixture of 126 grams of 98 per cent. anhydrous glycerin (which must be free from arsenic) with 200 c.cm. of distilled water; one drop of Ziehl's carbolized fuchsine is added for each c.cm. to ensure sterility. If desired, the solution can be further sterilized by autoclaving at 100° C. for half an hour. Large doses (10 to 20 c.cm.) should be injected quickly in about half a minute to obtain the best results. The injections should be repeated every eight days, with an interval of about a week between each treatment, till cure results; as a rule two to four treatments suffice. In the doses prescribed the mixture is not toxic or escharotic. The tolerance for it is perfect, no shock follows the injection, and the phlebosclerosis is rapid and complete. In the last few months 57 patients of all ages and both sexes have been satisfactorily treated by this method; details of four of these are given.

444 Treatment of Parotid Epithelioma

Tumours of the parotid are usually malignant and of grave prognosis. Rapid recurrence as a rule follows surgical intervention, and the radio-resistance of the neoplasms often renders radiation useless. J. BELOT and G. MÉNÉGAUX (*Journ. de Radiol. et d'Electrol.*, February, 1931, p. 90) report a case of epithelioma of the parotid in which cure has persisted for twenty-six months after irradiation. A woman, aged 62, had a small tumour in the left parotid region in front of the tragus. This was excised, and proved to be a muciparous epithelioma of cylindrome type, a tumour of restricted malignancy. After the operation a paresis in the upper distribution of the facial nerve ensued. A month later there was recurrence under the cicatrix, and intensive irradiation was then given; for four weeks 5,000 R were applied directly to the left side, and 3,000 R to the right in order to reduce the dose absorbed by the skin on the left. After this treatment the patient showed considerable asthenia and complained of great dryness of the mouth. At the present date there is no trace of any recurrence, the general health is excellent, and the facial paralysis has disappeared. Only a slight lacrymation and dryness of the mouth persist.

445 Vesical Tumours

R. F. MATHEWS (*Amer. Journ. Surg.*, February, 1931, p. 343) defines three groups of bladder tumours: (1) growths, either papillomatous or pedunculated, which project well into the bladder; (2) sessile growths which spread laterally along the bladder mucosa and project less into the bladder; and (3) infiltrating growths, which invade every layer of the bladder and of the surrounding bladder tissue. Bladder tumours are either benign, the papilloma being the most common of this type, or malignant, such as malignant papilloma, papillary carcinoma, adenocarcinoma, and epithelioma. The benign papilloma is always intravesical and begins as a tiny excrescence on the surface of the epithelium. Later on this frequently becomes malignant, with thickening of the epithelial layers, multiplication of the layers, and fusion of the papillae. Bladder tumours are most common in the region of the trigone and ureteral orifices, and occur in males and females in the proportion of 4 to 1. Secondary effects of bladder tumours are bleeding, obstruction in the ureter or urethra, necrosis, ulceration, encrustation, stone formation, infiltration of the bladder wall, and infection. Painless haematuria is usually the first and only symptom;

it occurs in 90 per cent. of cases. It is generally intermittent, and cystoscopy should be undertaken at a time when the bleeding has stopped in order that the tumour may more easily be identified. Treatment depends on the nature and location of the tumour; excision or resection did not relieve the condition, and in some cases aggravated the symptoms, there being superadded implantations and metastasis. Radium in the form of radon seeds, used in conjunction with other methods of treatment, has proved satisfactory. High-frequency current through the cystoscope, or by suprapubic operation, has worked well in apparently hopeless cases, and for benign growths fulguration with the bipolar high-frequency current is the treatment of choice. Deep *x*-ray therapy can be used successfully as an adjuvant to other types of treatment, and relieves pain. The mortality rate for all types of carcinomatous tumours of the bladder was 75 per cent.; in cases of malignant papilloma it was 12 per cent., and in cases of benign papilloma there were no deaths.

446 Treatment of Cancer of the Prostate and Bladder

A. SANCHIZ and A. TORRA HUBERTI (*Zeit. f. Urol.*, Heft 3, 1931, p. 196), who record six illustrative cases, conclude that the question of complete recovery in carcinoma of the bladder and prostate is not yet settled. Treatment by the insertion of radium tubes directly into the tumour masses appears to be correct, judging from the objective results and what is found on palpation. The chief indication for this procedure is to be found in early cases. In advanced cases, in which the technique is more dangerous, the treatment is not so clearly indicated. The hypogastric route appears to be the most suitable for the insertion of the radium tubes. At the present time a combined method of treatment seems to offer the best prospect—namely, the association of radium with the application of other physical agents or with a suitable surgical operation.

447 Chondromas of the Hand

F. J. VIDAL (*Rev. med. de Barcelona*, January, 1931, p. 34), who records two illustrative cases in girls aged 14 and 15, states that chondromas are comparatively rare tumours which are most frequently localized in the hand, and then in decreasing order of frequency in the scapula, femur, long bones, spine, ribs, cranium, bones of face, and hyoid. They are sometimes single, but are usually multiple, and form spherical, lobulated, or diffuse masses of homogeneous, semitransparent opaline tissue. The tumour may undergo a calcareous, cystic, or malignant change. Operation is indicated in the case of large chondromas, or for aesthetic reasons, as well as in cases in which malignant degeneration has occurred; it consists in removing the tumour and scraping the bone. The insertion of bone grafts, as recommended by Michon, is unnecessary.

448 Congenital Diaphragmatic Hernia

J. QUÉNU (*Bull. et Mém. Soc. Nat. de Chir.*, March 7th, 1931, p. 307) reports a case of congenital diaphragmatic hernia in a woman, aged 47, which was discovered after a fall. The first symptoms of pain and sickness occurred during the meal immediately following the fall, but they subsided and did not recur until a year later, when the patient was treated for cholecystitis and then for colitis. Further attacks of pain followed at intervals of a few months, and in each case the symptoms appeared at the end of a meal. There was acute pain in the epigastrium which was referred to the back and the left shoulder, and was accompanied by nausea and vomiting. The patient had lost weight, and radiography showed a bilocular stomach of which the upper pouch was above the diaphragm; a diagnosis of left diaphragmatic hernia was made. Laparotomy confirmed the *x*-ray and clinical findings that there was an incomplete herniation of the stomach through the diaphragm. At the operation it was found that the hernial opening was postero-internal at a little distance from the oesophageal orifice, that the opening would only admit two fingers, and that the hernia did not contain the large intestine. The thoracic portion of the stomach was drawn down into the abdomen, the hernial sac was resected, and the opening in the diaphragm was closed by interrupted sutures. Convalescence was comparatively uneventful, and the patient made a good recovery. Radiography six months later showed that the movement of the diaphragm had greatly improved.

449 Osteomyelitis Variolosa

C. F. EIKENBARY and J. F. LECOCQ (*Journ. Amer. Med. Assoc.*, February 21st, 1931, p. 585), who record three illustrative cases in children aged 7, 11, and 14, state that in addition to ordinary acute osteomyelitis the virus of small-pox may undoubtedly cause a non-suppurative osteomyelitis. The virus is situated apparently in the epiphyseal lines of the long bones; it produces an aseptic necrosis which chiefly affects the growing cartilage cells of the epiphyseal lines and causes premature closures. The diagnosis of osteomyelitis is often not made during the acute stage, and it is only after the acute attack that the deformities caused by inequality of the growth of the long bones show themselves. The deformities do not occur in adults because bone growth has ceased, and the small-pox virus apparently affects only the epiphyseal lines of bone. In obscure deformities of bone, therefore, a careful inquiry should be made as to an attack of small-pox in childhood.

Therapeutics

450 Nascent Iodine in Pulmonary Tuberculosis

J. G. MACKERETH (*New Zealand Med. Journ.*, February, 1931, p. 23) strongly commends the treatment of pulmonary tuberculosis with nascent iodine. In the first week he gives 10 grains of potassium iodide in 1 oz. of water at 7 a.m., following this two hours later with 1 oz. of liquor chlorini in half a pint of lemonade or water. In the second week the amount of potassium iodide is doubled; the chlorine dose is given at 9 a.m. and repeated at 11 a.m. In the third week the potassium iodide is increased to 30 grains, and three doses of the chlorine solution are administered at two-hourly intervals; this programme is then maintained so long as is found desirable, no further increases being necessary. The only untoward symptom noted was dyspepsia, generally in the form of the aggravation of pre-existing dyspeptic symptoms. In no case was dyspepsia originated by the treatment. In the first and second weeks there was some rise in temperature occasionally, and some increase in cough, but these symptoms were never alarming, and soon settled down. Beneficial results appeared within the first week in many cases, but improvement was usually not definite until the end of the third week, the toxic symptoms subsiding, and the bacilli beginning to disappear from the sputum. The author considers this form of treatment antiseptic rather than specific, but he denies that it is any less effective in primary tuberculous cases before the secondary organisms have appeared, provided that they are open cases. He believes that it is particularly indicated for the more advanced type of case, and should enable such patients to be restored more quickly from the hospital to ambulant treatment.

451 Combined Treatment of General Paralysis

A. JORDAN (*Rev. Méd. de la Suisse Romande*, February 25th, 1931, p. 99) describes the results obtained from stovarsol and malarial treatment in general paralysis of the insane. Between 1924 and 1928, 22 cases of general paralysis were treated with stovarsol; of these, 7 patients were mentally excited or megalomaniac, 9 were feeble-minded, and 6 had dementia. In the first group, three patients were able to resume social life, two were improved, and two remained stationary. In the second group, one patient became very much better, three were improved, three remained stationary, and two died. In the third group, one patient was much improved, four remained stationary, and one died. Jordan regards cachexia, heart disease, and active tuberculosis as contra-indications to stovarsol treatment; he employs various methods in selected cases—simple malarial infection, or a

subsequent course of arsenobenzol treatment, with or without malarial reinfection. Of fourteen patients who were first treated with malaria, next with prolonged stovarsal, and then again with malaria, five resumed social life (two relapsed but were cured subsequently), two recovered sufficiently to be discharged, another patient improved but died of intercurrent disease, and six patients remain stationary and are still under treatment. The author remarks that if these results are not considered so brilliant as others recorded elsewhere, the relative failure is due to the advanced stage of the disease in these patients on admission, and also to the fact that all patients whose physical health justified treatment (regardless of their mental condition) were inoculated. In spite of some inevitable failures, there have been interesting results and a notable amelioration in several cases, compared with the results obtained previously with tryparsamide. He considers that the combined method—stovarsol and malarial therapy—constitutes a real advance in the treatment of general paralysis of the insane.

452 Vaccine Treatment of Rheumatic Fever

R. SCHNABELE (*Acta Rheumatologica*, February, 1931, p. 35) records his observations on 94 cases of acute articular rheumatism in patients aged from 20 to 23 who have been under his care during the last three years. Of these, 69 had been treated by salicylates and 25 by Bertrand's vaccine. The results were as follows. Of the 69 patients treated by salicylates, 49 who had slight or moderate attacks made an uncomplicated recovery; 13 showed a protracted course, accompanied by persistent fever and pain, but ultimately recovered after a long convalescence and a state of pronounced anaemia, and with a heart that required watching; and 7 developed cardiac complications, or with intolerant of salicylates. Of the 25 patients treated by vaccine, all but one made an excellent recovery; six of them had previously been treated by salicylates without any result. A cure was usually obtained on the seventh to the ninth day without any cardiac complications or reaction.

453 Sodium Iodide in Herpes Zoster

E. W. REGGLES (*Arch. Derm. and Syph.*, March, 1931, p. 472) records fifteen cases of herpes zoster in which the intravenous administration of sodium iodide appeared to act as a specific, since they all cleared up in from ten to seventeen days with rapid relief of the pain. The contents of a 20 c.cm. ampoule containing 2 grams of sodium iodide were injected intravenously on the first, second, fourth, and seventh days, though two cases required only two injections and four only three. With the exception of one case in which the condition affected the left malar prominence, all were given quartz light and a dusting powder consisting of zinc oxide (½ oz.), camphor powder (1½ drachms), corn starch (1 oz.), and morphine sulphate (3 grains), which had been the author's method of treatment for several years previously, without any apparent effect beyond some amelioration of the pain. Richmond of Texas reported some years ago a case of ophthalmic zoster which cleared up in six days following two intravenous injections of 2 grams of sodium iodide.

454 Plasmoquine in Malaria

C. R. AMIES (*Bull. Inst. Med. Research Fed. Malay States*, 1930, No. 5) reports an investigation into the use of plasmoquine in subtertian malaria, with special reference to its effect on the viability of the gametocytes of *Plasmodium falciparum*, and on the development of the crescents. To 84 patients suffering from acute malaria were given 20-grain doses of quinine hydrochloride and two-thirds of a grain of plasmoquine daily for ten days. A small control series of 20 patients received the quinine doses without plasmoquine. While it seemed clear that plasmoquine could not prevent almost fully matured crescents from appearing in the peripheral blood, it was evident that gametocytes in the early stages of development were destroyed. No support was obtained for the view that this drug intensified the action of quinine on the asexual forms of *P. falciparum*, but Amies recommends that it should be administered as a preventive as soon as the patient comes under observation, since two doses, each of one-third grain, will render non-viable all the crescents in the blood of a carrier. Furthermore, the blood remains non-infective to mosquitos for at least three days, and therefore economy can be secured with safety by administering plasmoquine on every third day. The author thinks that the dosage of quinine could simultaneously be cut down to 20 grains daily, except in the more pernicious types. No toxaemia was caused by the treatment.

Neurology and Psychology

455 Bilateral Facial Paraspasm

L. STIENON (*Bruxelles-Médical*, March 22nd, 1931, p. 604) reports the case of a man, 72 years old, who was first attacked in 1916 by crises of contraction of both orbicularis palpebrarum muscles. These lasted for some months and then stopped, but shortly afterwards facial spasm developed. Both sterno-cleido-mastoid muscles became tense and contracted; the buccinators and all the facial muscles are affected by clonic, disordered movements. The patient carries his head inclined downwards and with a slight deviation to the right, and is unable to distinguish objects without forcibly opening the eyes. The face is fixed in a permanent grimace, and the labial commissures are spasmodically drawn outwards. These spasms cannot be controlled; efforts to do so increase them, and relief is only obtained by lying down. The patient is otherwise healthy. For some years he has suffered from a ranula, and when 20 years old contracted syphilis, of which he now shows no signs. This rare condition was first described by Sicard and Hagenau in 1925, and named by them bilateral facial paraspasm. Its etiology and pathology are quite unknown; syphilis is probably not a factor. It is apparently due to a dysfunction of the central nuclei of the facial nerves, and secondarily of other motor nuclei of the mesencephalon; in the present case the spinal medullary nucleus was also involved. Stienon points out the similarity of this disease to Parkinsonism in many respects. Both maladies are incurable and do not respond to any treatment. In bilateral facial paraspasm suggestion therapy alone appears to give some transitory relief.

456 Trauma of the Brachial Plexus and its Roots

Lesions in any part of the brachial plexus tend to produce a complex clinical picture owing to its complex origin, formation, and various other factors. Each case must be considered individually. L. M. TOCANTINS (*Journ. Nerv. and Ment. Dis.*, March, 1931, p. 258) describes a case in which the plexus was injured by violent traction, and external (or backward) rotation of the arm. Undoubtedly some laceration of the fascia and epineurium of the first thoracic root, and possibly of the eighth cervical, occurred with blood extravasation and stretching of the roots between the ganglia and the lower cord of the plexus. Another case is briefly cited in which depression of the pectoral girdle due to malunion of a fractured clavicle caused strangulation of the lower trunk on the first rib, and neuralgia and motor disabilities in the region supplied by the fifth cervical roots. Tocantins remarks that defective posture, caused by the original injury, as in the present cases, may be the chief factor in perpetuating the symptoms. It may give rise to the cervical rib syndrome, even though such rib is absent. From actual experience and a study of the literature, he concludes that in all cases where the syndrome of compression, traction, and irritation of the brachial plexus or its roots exists, with or without the presence of a cervical rib, vigorous corrective treatment should be applied by braces, exercises, and electrical stimulation. If a rib resection or a decompressive operation is thought necessary, this should be supplemented as far as practicable, unless the loss of muscle tone is due to discontinuity or degeneration of the nerve supply.

457 **Paralysis of the Cranial Nerves**

From a study of 213 cases, LL. H. ZIEGLER (*Minnesota Med.*, December, 1930, p. 880) demonstrates the significance of cranial nerve palsy, and discusses the signs of, and the conditions that may cause; paralysis of each nerve. Complete paralysis of an isolated nerve (except the fourth) is easily recognized; diagnosis is more difficult when more than one is affected. Much pain may exist in the distribution of a nerve such as the fifth or ninth, without demonstrable sensory or motor defects. Partial paralysis, especially of the third, fourth, and sixth nerves, has not been uncommon after influenza. Often the first symptom of nasopharyngeal tumour is pain over the distribution of the fifth nerve, which is usually involved early, the paralysis being generally confined to the side of the tumour. Retroparotid tumours commonly involve the ninth, tenth, eleventh, and sometimes the twelfth nerves, and produce the Jackson or jugular foramen syndrome. Tumours of the acoustic portion of the eighth nerve invariably involve the fifth on the side of the lesion. Syphilis and tuberculosis select especially the nerves to the optic muscles; fractures through the base the seventh and eighth nerves, though others also may be affected. In involvement of a motor nerve, a decision whether the muscle, nerve nucleus, or upper motor neurone is involved may be difficult, though the site of the lesion can often be determined. If the muscle is involved, consideration of its texture may be of value. Widely separated muscles may also exhibit signs of disease. If the nucleus is affected, atrophy and fibrillary twitchings are usually seen in the muscles supplied by the nerve. In lesions of the upper motor neurone, other signs (Hoffman's or Babinski's) are present. The patient's subjective sensations and reactions must be relied on in lesions of sensory nerves. Daily observation is most essential.

Obstetrics and Gynaecology

458 **Radium Treatment of Cancer of the Cervix**

O. CHIEVITZ (*Ugeskrift for Laeger*, February 26th, 1931, p. 208) reviews the results achieved at the radium station in Copenhagen in the 532 cases of cancer of the cervix admitted in the period 1921-27 inclusive. Ten of these cases were excluded from the analysis for various reasons, and two of the patients could not be traced. The condition was operable on the patient's admission (normal mobility of the uterus and no infiltration in the parametrium) in only 27 cases. There were 29 borderline cases. The 466 inoperable cases were classified in three groups, according to the degree of their severity, and as many as 336 were in the third or most inoperable group. It will thus be seen that the material consisted mostly of very advanced cases. About 60 per cent. of the operable and borderline patients came for treatment within three months of the first appearance of symptoms; this was the case in only about 30 per cent. of the inoperable cases. In about 60 per cent. of all the cases the doctor consulted had taken some effective step at once; in the remaining 40 per cent. he had temporized. Of the 27 operable patients kept under observation for at least three years, 19, or 70 per cent., were alive and symptom-free. Of the 29 borderline patients, 16, or 55 per cent., were alive and well after three years. As for the 466 patients in one or other of the three inoperable groups, it was found that 111, or 24 per cent., were alive and well three or more years later. Of the 263 patients with an observation period of at least five years, 51, or 19 per cent., were still alive; these were patients who before radiotherapy was introduced would have been irrevocably lost. When the operable, borderline, and inoperable cases were grouped in one class, it was found that 28 per cent. survived after three years, and 22 per cent. after five years. The author points out that in a comparison of his material with that of other radium institutions the preponderance of advanced cases in his institute should be borne in mind. While he had only 5 per cent. operable cases, Heyman of the Radium Institute in Stockholm had about 22 per cent. of such cases, and in Paris 40 per cent. of Regaud's material was operable when radium treatment was instituted. It would seem that in Denmark patients suffering from cancer of the cervix do not, as a rule, come for treatment, whatever be its character, before the disease has become inoperable.

459 G. G. WARD and LILIAN K. P. FARRAR (*Surg., Gynecol. and Obstet.*, February 15th, 1931, p. 356), reporting a series of 251 cases of cervical carcinoma treated with radium, remark that the leucopenia induced by this therapeutic method necessitates steps being taken to fortify the patient's resistance against septic infection, and so against the unpleasant sequels that may otherwise be associated with the absorption of the post-radiation slough. Each case is carefully examined at monthly intervals after radiation, in order to detect signs of early recurrence in the form of small nodules or erosions, and also to deal with the possible complication of pyometra in its first stages. The authors conclude, as the result of their eleven years' experience, that in carcinoma of the cervix the best results can be obtained by employing the smaller dosages of radium (2,400 to 4,200 mg.-hours), provided that the cases are re-examined at frequent intervals during the subsequent five years, and that recurrences are dealt with at once by renewed radiation. Any cachexia or anaemia should always be treated in advance by blood transfusion if the red corpuscles have fallen below 3,500,000 per c.mm. and the haemoglobin percentage below 50. They hope that high-voltage *x*-ray therapy will prove efficacious in dealing with the 40 per cent. incidence of gland involvement in the advanced cases. In all patients whose disease has progressed beyond the cervix, surgery is prohibited, they add; the authors' own results with radium have been fully equal to the surgical figures of successes, but without the high primary mortality and morbidity. They doubt whether the method of following radium treatment by vaginal hysterectomy and *x*-radiation gives results good enough to compensate for the high primary mortality of this procedure.

460 **Hormone Treatment of Morbid Menstrual Conditions**

According to R. KÖHLER (*Zentralbl. f. Gynäk.*, February 14th, 1931, p. 415) the ovarian preparations which were available before the methods of standardization introduced by Allen and Doisy and Zondek and Aschheim contained ovarian hormone in insignificant amounts, and owed any therapeutic potency which they possessed to their content of foreign proteins, amines, and choline-like substances. As an illustration, the paradoxical findings are reported that uterine bleedings were successfully stopped, in 103 of 142 patients, by a hormone preparation prepared and recommended for the treatment of amenorrhoea; amenorrhoea ceased in 16 out of 24 young women treated by a hormone preparation found effective in the cure of metrostaxis. Using with the recommended therapeutic purpose small doses of the newer and standardized ovarian hormone preparations, Köhler has had favourable results in cases of amenorrhoea, but he has not found the new ovarian or anterior pituitary preparations to be of use in the treatment of dysmenorrhoea. In eight out of ten hypoplastic patients with excessive uterine bleeding, cure followed treatment by the injection of insulin.

461 **Preventability of Eclampsia**

J. P. S. JAMESON (*New Zealand Med. Journ.*, February, 1931, p. 18), commenting on the reports of eclampsia cases for the year 1929, points out that the previous absence of albuminuria affords no certainty that eclampsia may not ensue. In six cases recently examined albumin did not appear in the urine until the day of the eclamptic attack; in one it did not appear until after the attack, and in four cases there was no albuminuria at any time. Out of a total of 84 cases during the year there was a history of previous kidney disease in 7 cases, two of these patients died, a mortality rate of 28·6, as compared with 17 per cent. among those who had not had renal trouble before the eclampsia. The author found cases

of eclamptic attacks coming on entirely unexpectedly in apparently healthy women, instances where approved treatment had failed to arrest the condition in the pre-eclamptic stage, and cases where, after an apparent yielding to treatment at first, there had been a subsequent active flare-up. He concludes, therefore, that this condition is not always preventable in the present state of knowledge.

Pathology

462 Blood Changes during Pregnancy and Parturition

R. REDING and A. SLOSSE (*Bruxelles-Médical*, March 1st, 1931, p. 503) report a series of observations on the changes in the blood reaction, calcium content, and the alkaline reserve during pregnancy and parturition. They suggest that the physiological alkalosis which occurs at the end of gestation and parturition favours the division of malignant cells. The *p*H was estimated by Cullen's colorimetric procedure, and also by Kerridge's method. The total carbonic acid and alkaline reserve were measured by the volumetric apparatus of van Slyke, and the calcium figure was calculated by the formula of Rona and Takahashi. Examinations were made of 72 normal women at monthly intervals during gestation, at the time of parturition, and during the following weeks. The readings showed that the reaction of the blood remained normal until the seventh month, when it began to move slightly towards an alkalosis at the time of parturition, falling during the following weeks and becoming normal again after six months. The alkaline reserve was lowered halfway through pregnancy, and remained so until the first week after the confinement. The calcium content was lowered progressively during the second half of pregnancy, and did not return to the normal until after parturition. Other modifications, such as the colloidal instability of the blood and changes in the surface tension and the permeability of the cellular membrane, appeared at the same period of gestation. The authors suggest that these humoral modifications may throw light on the nature of predisposition to microbial infections at the time of parturition.

463 Glutathione in Ether Narcosis

E. RUGGIERI (*Arch. Ital. di Chir.*, January 31st, 1931, p. 69) describes certain experiments he carried out with regard to the behaviour of glutathione (a dipeptide made up of cystin and glutamic acid) in relation to ether narcosis. He examined the glutathione content in 21 cases before and after operation, and found definite diminution invariably. The length of the operation had apparently little bearing on the result. He examined a few cases of operation under spinal or local anaesthesia so as to eliminate the ether factor; these also showed some diminution of glutathione, but to a far less marked extent, 0.84 as compared with 5.17 mg. after ether. It seems probable that the ether acts directly on the red corpuscles and therefore interferes with organic oxidation. This action very likely plays an important part in post-operative pulmonary affections and in acidosis; it may also partly account for post-anaesthetic hyperglycaemia.

464 The Velocity of the Blood Flow

H. L. BLUMGART (*Medicine*, February, 1931, p. 1) discusses the work of many investigators of the speed of the blood flow in health and disease, and describes the method he has personally employed to determine this velocity. The principle of the method is the injection of radium C, the active deposit of radium, into the antecubital vein, the time of arrival in the other arm being determined by a suitable detecting device. The detection of beta and gamma radiations depends on the fact that these radiations cause ionization of any gas they traverse, and the onset of ionization in a gas is an indication of the presence of the radiation of a member of the radio-active series. By means of a cloud chamber and a modification of the Geiger counting chamber it is possible to estimate the circulating time from the antecubital vein of one arm to the antecubital artery of the other arm, and also to make an automatic registration of the time of arrival of the active deposit in the right heart—"the arm-to-heart time"; the interval between the arrival of active deposit in the right heart and the arteries about the elbow is called the "crude pulmonary circulation time." The advantages and disadvantages of the histamine method are also discussed.

465 Plasma Volume and Acute Infections

E. BUCCIANTI (*Il Policlinico*, Sez. Med., March 1st, 1931, p. 138) has observed variations in the plasma volume of the circulating blood in cases of acute infectious diseases. His examinations included 16 cases of pneumonia, 9 of malaria, and 5 of acute general tuberculosis. The Congo-red method for estimating the blood volume was used. It was assumed that the total blood volume was 7 to 7.5 per cent. of the body weight, the plasma volume was 4 to 4.5 per cent., the blood cells 3 per cent., and the ratio of plasma to cells was 54 to 46 per cent. Buccianti found the greatest variations in the plasma in pneumonia; there was a marked increase during the acute phase which fell to normal or below after the crisis, demonstrating clearly a plasmatic plethora during the febrile period. A similar hyperplasmia was shown in the experimental fever produced by malaria in neurosyphilis, and also in the cases of general tuberculosis. These variations in the plasma volume are linked up with the hydrophilic capacity, and with the protein concentration. The corpuscular content of the blood was unrelated to variations of the plasma volume, but maintained in all cases a level slightly below the normal; a definite fall in the corpuscle content was noted in some cases. Hyperplasmia and a corpuscular diminution during the course of an infection represent, according to Buccianti, an adaptation of the circulating blood to the disease.

466 The Effect of Anaesthesia on Paroxysmal Conditions

D. DANIELOPOLU (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 9th, 1931, p. 324), alluding to the work of Troisier and Bouquien on the amelioration of bronchial asthma after general anaesthesia, suggests that spontaneous epilepsy, angina pectoris, and the gastric crises of tabes (all being conditions associated with hyperexcitation of the sympathetic system) may similarly be influenced. Surgical measures for the relief of the last three conditions have been attended by some degree of success, permanent relief being obtained in some cases; this occurs in spite of the fact that the main object of the operations—namely, complete destruction of the part of the sympathetic system involved in the pathological reaction—is seldom achieved. Danielopolu believes that anaesthesia (whether general or spinal) associated with operative shock has a great influence in lowering the sympathetic tone; he ascribes to this the cessation of symptoms so often observed for seven to fifteen days after an operation, whether or not permanent relief ensues. He considers that the stage following this quiescent one, when attacks may recur for a while, is due to traumatic excitation of the sympathetic, and is comparable with post-amputation neuralgias. The lowering of the tonus is well shown by a measurable fall in the blood pressure. He is inclined to ascribe any permanently good results not to complete destruction of part of the reflex arc, but to a temporary break in the vicious circle by the lowering of the tonus by the anaesthesia and shock. As an example of the beneficial results obtained by such a break in a vicious circle, he describes the great reduction in the frequency of attacks of angina obtained after local anaesthesia of the intercostal nerves; if only one expected attack can be averted, the hyperexcitable state of the sympathetic system is reduced. Referring to the cessation of asthmatic and epileptic attacks during febrile states, he concludes that the sympathetic tonus is lowered for the time being, the failure of the subject to react to subcutaneous doses of adrenaline being an index of the fall.

What three doctors say about Odol

1. STOMATITIS

"I have often recommended Odol to patients suffering from Stomatitis and have found it very efficacious."

....., M.R.C.S.Eng., L.R.C.P.Lond.

2. NOSE WORK

"I use a solution of Odol for all nose work, washing out the antrum and sinuses, etc. It is excellent and a soothing antiseptic."

....., M.D.

3. ZYMOTIC DISEASES

"It is most excellent in septic conditions of the mouth such as one finds in the zymotic diseases."

....., M.C., L.R.C.P., M.D.H.

Not only is Odol definitely antiseptic—not only does it destroy disease germs of the mouth and throat—not only does it check the growth of bacteria for hours after use—but it is perfectly safe. Non-toxic, non-caustic, and non-acid, Odol does not injure the teeth or the mucous membrane of the mouth.

Samples and literature will gladly be sent to any member of the Medical Profession on application to:

CRANBUX LIMITED OF NORWICH

Aldwych

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me"*; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

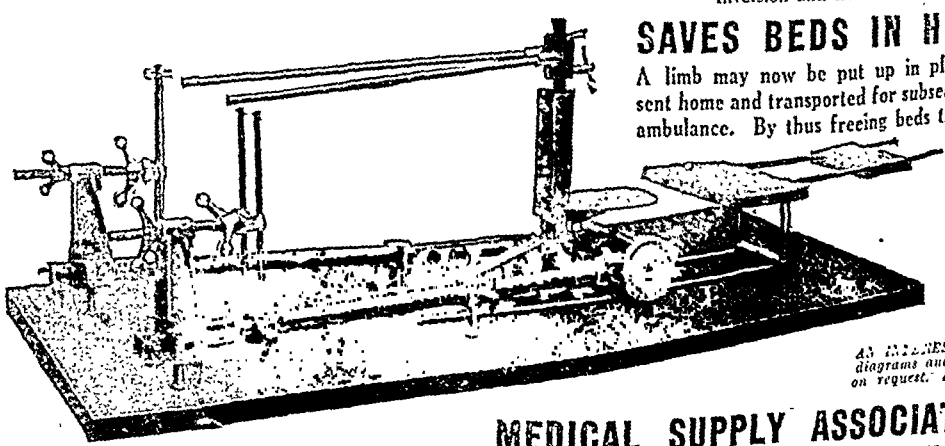
An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alternative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte St., London, E.C.2.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

THE
DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

REGISTERED NURSING HOME
for
PERMANENT PATIENTS.
3, Brondhurst Gdns., London, N.W.6.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark. 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for *hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion* bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

Phone: 11 Ashton in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

The MUNDESLEY SANATORIUM

The newly opened central building makes the Mundesley Sanatorium the best equipped building in England for the cure of Tuberculosis. All the bedrooms have hot and cold running water, electric light, and wireless head-phones. The new public rooms are spacious and comfortable.

Resident Physicians:
S. VERE PEARSON, M.D.(Cantab.), M.R.C.P.(Lond.).
L. WHITTAKER SHARP, M.B.(Cantab.).
ANDREW MORLAND, M.D., M.R.C.P.(Lond.).

For all information apply:
THE SANATORIUM, MUNDESLEY, NORFOLK.
(Telephone: Mundesley 4.)

The buildings face S.S.W. and are sheltered from the sea by a pine-clad ridge. The sunshine record and dry air complete a perfect site. The medical equipment is of the latest kind, and there is a day and night nursing staff.

VALE OF CLWYD SANATORIUM

This Sanatorium is established for the treatment of TUBERCULOSIS of the LUNGS and the PLEURAL CAVITIES. It is situated in the midst of a large area of park-land at a height of 450 feet above sea-level on the south-west slopes of mountains rising to over 1,800 feet, which protect it from north and east winds and provide many miles of graduated walks with magnificent views. Average rainfall 29.57 per annum. Full day and night nursing staffs. X-ray plant. Every facility for Artificial Pneumothorax and for operations on the chest. Electric lighting. Central heating. Home farm. Clean milk from T.T. Herd. For particulars apply to Med. Supt., H. Morriston Davies, M.D., M.Ch.Cantab., F.R.C.S., Llanbedr Hall, Ruthin, N. Wales.

PENDYFFRYN HALL SANATORIUM
PENMAENMAWR.

Established 1900 for the treatment of Tuberculosis. Miles of carefully graduated walks through pine-clad hills, with sea and mountain views. Modern treatment, including SANOCRYSIN, ARTIFICIAL PNEUMOTHORAX, etc. X-ray plant, electric light, central heating, wireless. Special milk supply from tuberculin-tested herd. Full day and night nursing staff. On L.M.S. Main Line to Holyhead, 4¼ hours from London. Resident Physicians: Dennison Pickering, M.D.(Cantab.), A. C. Armstrong, M.B.; Matron: Miss S. A. Eddy, S.R.N., Late Sister-in-Charge, Royal Hospital Annexe, Sheffield.

For particulars apply to the Secretary, Pendyffryn Hall, Penmaenmawr, N. Wales. ('Phone, 20.)

THE COTSWOLD SANATORIUM

Specially built in 1893 on the Cotswold Hills, seven miles from Cheltenham, for the treatment of Pulmonary and all other forms of Tuberculosis. Aspect S.S.W., sheltered from North and East, elevation 800 feet. Pure bracing air. Special Treatment by artificial Pneumothorax (X-ray controlled), Tuberculins, Medicated Inhalations by means of the Apneu Inhalation Installation, and Ultra-Violet Rays is available, when necessary, without extra charge. X-ray plant. Electric light. Radiators, hot and cold basins, and Wireless in all rooms. Full day and night Nursing Staff.

Resident Physicians: GEOFFREY A. HOFFMAN, B.A., M.B., T.C.Dub., and MARGARET A. HARRISON, M.B., B.S.Lond.

Apply: The Secretary, The Cotswold Sanatorium, Cranham, Gloucester. *Telephone:* 41 WITCOMBE. *Telegrams:* "HOFFMAN, BIRDLIP."

EAST ANGLIAN SANATORIUM

This Sanatorium was specially built for the treatment of Pulmonary and other forms of Tuberculosis, and has an ideal situation facing S.S.E. in a very sunny district. Special treatment by artificial Pneumothorax (X-ray controlled). Ultra-violet Ray treatment is available for suitable cases. Matron and full nursing staff. Nurse on duty all night. Electric lighting throughout, radiators and wireless (headphones) in all rooms.

Dr. Jane Walker, C.H., J.P., Medical Superintendent. Dr. Eleanor Soltau, Assistant Medical Superintendent.

For all information apply: The Secretary, East Anglian Sanatorium, Nayland, near Colchester.

Telephone: NAYLAND 1.

HARROGATE

for the Treatment of RHEUMATISM, ARTHRITIS, FIBROSITIS, NEURITIS, Diseases of the LIVER and GALL BLADDER, GASTRIC CATARRH and COLITIS, SKIN DISEASES, ANAEMIA and Convalescence from Acute Illness.

SULPHUR, Saline Iron and Pure Chalybeate waters, together with the presence of large deposits of Volcanic Mud, enable Harrogate to offer every facility for the cure of an unusually wide range of the diseases amenable to Spa Treatment.

The Harrogate Royal Baths, housed in one of the finest Spa buildings in Europe, are equipped with the most modern apparatus for all forms of Physiotherapy.

THE "CURE" is taken in a holiday environment: three golf courses, putting greens, hard tennis court, swimming baths, beautiful gardens and moorlands encourage sport and exercise.

First-class hotels, hydros, boarding houses and private apartments meet all requirements for accommodation.

Harrogate is an ideal holiday centre and is surrounded by some of the most beautiful scenery in England.

Applications to be made to the undersigned not later than Monday, May 11th, 1931.

J. COURTNEY BUCHANAN, Secretary.

Borough of Ilford.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invites applications from legally qualified Medical persons of both sexes *for the office of Assistant Medical Officer of* Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates for the appointment must have had special experience in Midwifery and Ante-natal work since qualification, and subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had definite experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus), rising by one annual increment of £50, and two annual increments of £25, to £700 per annum.

The person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Corporation's Maternity Home, and to enter into an agreement for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a *satisfactory medical examination*, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Thursday, May 14th.

Canvassing members of the Council, directly or indirectly, is prohibited and will disqualify.

By Order,

Town Hall, ADAM PARTINGTON,
Ilford. *Town Clerk.*
April 24th, 1931.

County Borough of Barrow-in-Furness.

WOMAN ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners for the position of Woman Assistant Medical Officer. The duties will be in connection with the Maternity and Child Welfare work of the Borough and the Medical Inspection of School Children.

Previous experience of Ante-natal and Maternity and Child Welfare work is essential.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700 per annum.

The officer will be required to work under the direction and supervision of the Medical *Officer of Health, and to devote whole time* service to the Corporation.

Copies of duties may be obtained on application to the Medical Officer of Health

Applications, stating age, qualifications, and experience, accompanied by copies of three recent testimonials, and endorsed "Assistant Medical Officer," must be delivered at the office of the undersigned not later than Thursday, May 14th.

Town Hall, W. A. CHISLETT,
Barrow-in-Furness. Town Clerk.

ASSOCIATION OF MEDICAL MEN RECEIVING RESIDENT PATIENTS.

This Association has been in abeyance since 1914, and the Hon. Secretary died several years ago. The President, Co-Trustees, and Hon. Treasurer hereby call a General Meeting at the Wilton Hotel, Victoria, London, at 3 p.m., on May 20th, 1931, when resolutions will be submitted (1) to wind up Association, (2) to hand over surplus assets to a Medical Charity.

Notice of Meeting will be sent to members who can be traced. Those not so notified are asked to notify the Hon. Acting Secretary, 75, Gunterstone Road, London, W.14 (1) of their intention of being present, (2) of their approval or otherwise of the above resolutions; or the President, J. WHEELER O'BRIEN, M.D., 29, Manor House, Marylebone, London, N.W.1.

Administrative County of LONDON.

HOSPITAL LABORATORY SERVICE.

The LONDON COUNTY COUNCIL invites applications from Medical Practitioners with appropriate qualifi
three positions of
Group Laboratorie
Brook Street, Kennington, S.E.5, [illegible] HOSPITAL, S.E.15, and ARCHWAY HOSPITAL, Archway Road, N.19. The scale of salary attached to the positions is £1,100, rising by increments of £50 to £1,500 a year. Candidates must be not less than 30 and not more than 50 years of age on the latest date for receiving applications. In the case of a woman, marriage terminates contract of service. The Group Laboratories are fully equipped, and each Pathologist will be responsible for the organisation and development of the pathological work for the Council's general hospitals in the Group (about 2,000 beds). The work is mainly Bacteriological and Biochemical, although Histological examinations will be carried out. The Pathologist will be expected to visit each Hospital of his Group at frequent intervals, and act generally as a consulting Pathologist to the Group. He will also be expected to carry out research work as opportunities arise.

Forms of application and further details may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division 4a), The County Hall, Westminster Bridge, S.E.1, and must be returned by May 29th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

Kettering Urban District Council

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants. Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—COUNTRY TOWN.—Within 130 miles North of London.—A fifth share, representing about £1,500 p.a., is offered in a particularly sound good mixed-class Practice, having substantial panel. Fees from 4/-. Not much midwifery. Suitable accommodation available. Premium 2 years' purchase. Ingoing partner should be a keen worker, and preferably Scotch or English.

2. LONDON (WEST END).—Old-established non-dispensing and non-panel PRACTICE, averaging over £4,700 p.a. Visits (very few) and consultations from one guinea upwards. No midwifery. Suitable accommodation available on rental. Premium £6,000. Good introduction given. Personal application desired.

3. NORTHERN CATHEDRAL CITY. — Old-established good mixed-class PRACTICE, averaging over £1,100 p.a., including panel of 1,070. Fees from 3/6. Not much midwifery from 2 to 10 gns. Very suitable small house, with 1 sitting, 3 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Good sport and first-class schools. Hospital, and prospect of appointment on staff. Premium for prompt sale £1,550 cash.

4. LANCS.—LARGE TOWN.—PARTNERSHIP.—A one-third or two-fifths share is for disposal in well-established and increasing middle and working-class Practice. Gross cash receipts for immediate past 12 months £3,150. Panel of over 3,000. Appts. worth about £80 p.a. Fees from 2/6. Choice of two houses, both at moderate rentals. Premium only 1½ years' purchase.

5. WITHIN 20 MILES OF LONDON (WEST).—Rapidly developing district.—PARTNERSHIP.—A half share in a well-established good middle-class Practice, averaging over £3,500 p.a. Panel of 1,100 and appts. worth £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.

6. SURREY.—COUNTRY PRACTICE.—Very old-established, and situated in delightful district. Gross cash receipts for past 12 months £2,000, including panel of about 700. Fees from 2/6 to 21/-. Midwifery 3 to 20 gns. Exceptionally nice house, with 2 reception, 6 bedrooms, *and professional rooms. Nearly 2 acres of garden. Price, freehold,* £3,000, £1,800 on mortgage. Premium £3,000.

7. CHESHIRE.—NEAR COAST.—Old-established good mixed-class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,280. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. *Rent on lease £85 p.a. Premium £2,300.*

8. PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase *later, of an old-established mixed-class Practice offering good scope.* Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium 2 years' purchase. Ingoing partner should be about 30, English or Scotch, and pref. married.

9. WITHIN 30 MILES OF LONDON.—In a [illegible] (well populated and growing rapidly), a [illegible] last year £406, including panel of 300, development. Very good residence (suit: about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400. Excellent schools, good society, and sport.

10. FAVOURITE COAST TOWN.—Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 3/6 to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. large garden. *Freehold for sale.* Premium £5,000.

11. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.

12. DEATH VACANCY.—LANCS.—LARGE TOWN.—Old-established PRACTICE, averaging about £500 p.a., but capable of much increase as district is growing. Panel of 250. Fees 3/6 to 10/6. Suitable accommodation can be secured. Premium £500 or near offer.

13. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.

14. PARTNERSHIP.—SOUTH-WEST LONDON.—A one-third share is for disposal in very *well-established chiefly middle-class Practice*, producing last year about £2,500, including panel (rapidly increasing) of 1,000. Fees from 2/6. Suitable house can be rented on lease. Premium 2 years' purchase.

15. PARTNERSHIP.—MIDLANDS.—Prosperous Town within 80 miles of London.—A *one-third or five-twelfths share* is for disposal owing to the retirement of the second of three partners in an exceptionally sound mixed-class Practice. Average gross cash receipts £5,300 p.a., including panel of 1,000. Fees 2/6 to 25/-, medicine extra. Premium only 1½ years' purchase for quick sale, owing ill health.

16. LONDON, WEST CENTRAL.—Old-established and increasingly mixed-class PRACTICE, producing for immediate past 12 months £1,790, including panel of 1,390. Fees 2/6 to 10/6. No midwifery. House in excellent repair, contains 2 reception, 4 bedrooms, bathroom, etc. Price for freehold £2,500. Premium 2 years' purchase.

17. LONDON, EAST.—Well-established mixed-class PRACTICE, averaging about £1,150 p.a., including panel of 1,400. Small house, with 1 reception, 2 bedrooms, etc., and 3 professional rooms. Rent on lease £13 per quarter. Premium £2,000.

18. *SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing* PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow *residence in about one acre of ground. Rent £84 on lease. Premium* £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy *instalments. Excellent climate and sport.*

19. NORTH [illegible] one-third share is offered in a good m [illegible] over £1,700 p.a., including panel of [illegible] p.a. Fees 3/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. *Premium 2 years' purchase.*

20. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. *Premium* 1½ years' purchase.

21. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. *Premium only* 1 year's purchase. Ill-health reason of sale.

22. SOUTH-WEST OF ENGLAND.—Near the Sea.—Old-established unopposed and easily worked Country PRACTICE, in beautiful district, within easy reach of Market Town. Receipts just under £1,100 p.a., including appts. and panel £550. Exceptionally attractive house in three acres of ground, with ample accommodation. Water laid on *and electric light available shortly. Price* freehold £2,600, part on mortgage. Premium £1,600. Sport and schools within reach.

23. YORKS.—LARGE TOWN.—Old-established chiefly good working class PRACTICE *averaging about* £1,300 p.a., *including* panel of 1,400. Fees from 2/6. Suitable house, with 3 reception, 4 bedrooms, and *dressing room*, etc. Garden; garage. Price £1,200. Premium 1½ years' purchase, chiefly by instalments.

24. LONDON, SOUTH-EAST. — Woman Doctor's PRACTICE, producing £560 immediate past 12 *months. Panel of* 152. Fees 2/6 to 21/-. Suitable flat can be rented at £60 p.a. Premium £650, or near offer. *Very good scope* for increase.

25. YORKS. — HOSPITAL TOWN. — Old-established sound *middle and* working-class PRACTICE, producing about £1,300 p.a., including panel of 1,300, and appts. worth £50. *Fees from 3/6. Small house* with one reception, 3 bedrooms, boxroom, etc. Premium 1 to 1½ yrs.' purchase, payable by *arrangement.* Ill-health reason for sale.

26. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. *Fees* 3/6 to 21/-. Practically unopposed. *Good modern house, with* special professional rooms. Nice garden. Garage. *Freehold for sale,* part *on mortgage. Good sport and schools within reach. Premium* 1½ years' purchase.

27. NORTH OF ENGLAND.—*GOOD TOWN.—A one-third share is offered* in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.

28. NEAR HEREFORDSHIRE BORDER.—*A one-third to one-half share in a well-established good-class non-dispensing* PRACTICE, producing about £1,800 p.a. Panel of over 500. *Good house* can be rented at £60 p.a. *Sport of all kinds. Premium* 1½ years' purchase, part *by instalments. Welsh not necessary.*

29. CHESHIRE.—*COAST TOWN, within reach of Liverpool.*—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.

30. *CORNWALL.—VILLAGE PRACTICE*, within easy reach of Plymouth — PARTNERSHIP.—A one-half share in a very old-established mixed-class Practice, averaging £2,563 p.a., including panel of 850. Fees 3/6 to 21/-. Not much midwifery. Good house, with 3 reception, 6 bedrooms, etc. Large garden. Price for freehold £2,000. *Sport of* all kinds. Premium 1½ years' purchase.

NIGHT OR MORNING?
WHEN TO TAKE LAXATIVES

There can, of course, be no universal rule as to the taking of laxatives. Circumstances vary, and only the physician is in a position to judge their relevance. But experience seems to show that a good deal of harm is often done by the common habit, continued over long periods, of taking aperients at bed-time. At night, the colon is normally much less active than in the day; and it seems unwise, unless special reasons exist, to stir it to unwonted activity during the hours which should be allotted to sleep. It is probable that much insomnia and many rest-disturbing dreams have their origin in the taking of a nightly purgative.

When there is an habitual tendency even to slight constipation, not fully remedied by diet and exercise, it is suggested that the most satisfactory result can generally be obtained by the taking, first thing in the morning, on an empty stomach, of a simple refreshing saline draught, such as Eno's "Fruit Salt" provides. Eno is a saline effervescent of fine granular consistency, containing no trace of irritating mineral salts, such as Epsom and Glauber. Owing to its purity and texture, it is agreeable to the palate; its pleasantness owing nothing to added sugar or flavouring matter, from both of which it is entirely free.

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

ACUTE LYMPHADENITIS

ACUTE lymphadenitis in children is a frequent, and sometimes dangerous, condition, which, however, can often be satisfactorily treated with the avoidance of operative measures. In addition to passive hyperæmia and iodine, the continuous application of moist heat, without the occurrence of alternating periods of heat and cold, is an essential measure. Antiphlogistine offers one of the best methods for applying continuous moist heat. Spread in a hot, thick layer over the affected area, this treatment will often result in reduction of the lymphadenitis in a short period of time.

SCIENCE AND PERSONALITY

By WILLIAM BROWN, M.A., M.D.(Oxon.), F.R.C.P., D.Sc.(Lond.),

Wilde Reader in Mental Philosophy in the University of Oxford; Psychotherapist to King's College Hospital, London; Hon. Consulting Psychologist and Lecturer on Medical Psychology, Bethlem Royal Hospital, London

Pp. 266. With a Foreword by Sir OLIVER LODGE, D.Sc., F.R.S. 12s. 6d. net.

Contents include: The Physical Sciences—The Biological and Psychological Sciences—Mental Unity and Mental Dissociation—Mind and the Theory of Conditioned Reflexes—Association, Dissociation, and Repression—Instinct, Sentiment, and Value—Theories of Suggestion—The Influence of Mind on Body—The Unconscious Mind—Theories of Mental Analysis—Mental Analysis and Psychotherapy—Suggestion and Will—Religion and Health—Personality and Art—Personality and Psychical Research—Faith, Love, and Personality.

"Dr. William Brown has always shown in his writings the catholicity of his mind. . . . He covers the whole field of the sciences from mathematics to the normative studies of ethics and aesthetics; rightly so, since his thesis is that man's highest pursuits are the Good, the True, and the Beautiful."—THE LANCET.

"Dr. Brown shows a greater maturity of thought and writes with a surer hand than before. The result is a work of very real scientific interest and value, especially to those who are called upon to deal with the maladjustments of modern life."—MEDICAL OFFICER.

"Dr. Brown performs a useful service in emphasizing the importance of the intellect as a factor of instinctive force, and by calling attention to the unwarrantedly complete depreciation of intellectual constructions by Freudian theory. The writing is clear, and the book should appeal very much."—JOURNAL OF NEUROLOGY AND PSYCHOPATHOLOGY.

OXFORD UNIVERSITY PRESS (Humphrey Milford), Amen House, London, E.C.4

Pp. x + 80. Crown 8vo. 6s. net: postage 3d.

KEROL CAPSULES

Announcement of the British Medical Association

• British
• Medical
• Journal

EVERY special issue of the British Medical Journal may be expected to provide material of interest to a large proportion of the profession. The next Special Number, to be published on June 6th, will include among its principal contents two recent lectures of much importance, one of them being accompanied by coloured illustrations on art paper plates. Original articles and clinical memoranda, covering a wide field of practice, will also be published together with full information about the Annual Meeting of the British Medical Association to be held at Eastbourne in July.

Mention may be made here of the carefully compiled advertisement sections in the Special Number. Readers have, at all times, shown their appreciation of advertisements appearing in these columns, and it is well known that their practical support has contributed to the high regard in which the British Medical Journal is held throughout the Advertising world. The advertisements published week by week constitute, in effect, an exhibition of current medical and surgical requisites which the doctor mindful of his obligations cannot fail to examine, for this is the recognized channel through which information about the accessories to practice may be obtained.

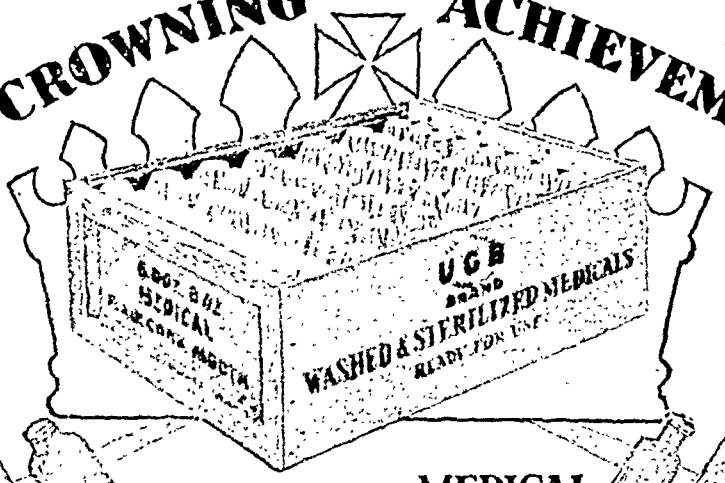
• Special
• Number
• June 6th

The forthcoming Special Number replaces the usual issue due to appear on the same date, and it will be sent to all members of the British Medical Association in the customary way. Despite the higher cost of production, due to reproductions in colour, there will be no increase in the normal charge of 1s. 3d. per copy made in respect of copies purchased by non-members.

• *Enquiries concerning the Journal should be addressed to :—*

The Manager, British Medical Journal,
B.M.A. House, Tavistock Square, London, W.C.1

THE CROWNING ACHIEVEMENT



U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

When a life is at stake....

The psychological moment has arrived. Will the operation be successful? . . . Can modern science triumph over such disease? . . . The surgeon bends closer over the table . . . deft fingers touching slender instruments . . . a life is at stake . . . if the lights should fail, plunging the theatre into darkness . . .

Nowhere is reliable light supply more important than in operating theatres. A light failure may have far-reaching consequences. Every hospital should be equipped with Ediswan Stationary Battery. Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately.

The Ediswan Stationary Battery for Emergency Lighting is compact and robust. It takes up little space and is sturdily built to give long service. Running costs are almost negligible. Installation costs are low.

May we co-operate with you in evolving a Battery specially to suit your requirements?

SALT

SERVICE IN SPECIALISATION

In the present age, when strenuous exercise is so prevalent, the danger of discarding elastic hosiery is obvious to Medical Men.

In order to prevent this risk we have produced our famous

DRESS SILK HOSIERY

which is inconspicuous when worn under the fashionable silk stockings of to-day.

This "dress silk" hosiery is composed of a special fabric, manufactured from the finest China silk with rubber strands, and is naturally more expensive and not suitable for rough usage.

We supply, however, 10 qualities of Elastic Hosiery in 8 different colours, to meet the requirements of all classes of patients.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassium Sodii Citro Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

The "Allenburys"
"CHARKAOLIN"
GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

OVALTINE

FOR THE GROWING CHILD

"Ovaltine" is indicated as a means of promoting normal growth and development when the weight of the child under observation is less than that which statistics show a child of the same height should weigh.

The physician has only to consider the composition and properties of the product to recognize how suitable it is as a building and reconstructive nutrient.

"Ovaltine" is a concentrated extraction of malt, milk, and eggs in the form of golden brown granules. For tissue growth or repair it provides proteins, mineral constituents, adequate energy value, and the Accessory Growth Factors or Vitamins in correct nutritive ratio.

Children love the deliciousness of "Ovaltine" and thrive remarkably well upon this complete food. It is of unsurpassable value as a meal-time beverage in place of tea, coffee, cocoa, or other beverages.

A liberal supply for clinical trial sent free on request.

Regesan

CREAM of MAGNESIA with LIQUID PARAFFIN

(CONTAINS 30% LIQUID PARAFFIN)

A STABLE well-balanced combination containing 30% Liquid Paraffin held in suspension in a finely divided state. Its consistency is such that the tendency to leak exhibited by Liquid Paraffin is eliminated. Regesan Cream of Magnesia with Liquid Paraffin provides suitable treatment for all digestive troubles with which constipation and hæmorrhoids are associated. It is certainly the ideal laxative during pregnancy and lactation, and is suitable for infants and children.

Medisoap

MIDGLEY'S MEDICATED SOAP Reg.

The word MEDISOAP is a registered trade-mark indicating the pure soap base made and scientifically medicated by CHARLES MIDGLEY, LTD., according to published formulae. This method of skin medication has been brought into favour by the ease with which applications can be made and the certainty of absorption through regularity of use by the patient.

A PRESCRIBER'S INDEX

relative to the comprehensive range of Medisoaps is available to members of the medical profession on application to EVANS' BIOLOGICAL INSTITUTE, RUNCORN.

Medisoap Depots all over the country.

Sole Makers:

ACNE

As an adjuvant in the treatment of this condition there are a number of Medisoap formulae recommended by many practitioners, and patients prefer this treatment to the disfiguring effects of ointments.

MEDISOAP No. 18, containing Naphthol 2½ and Sulphur 10%, used with success in Acne Vulgaris.

MEDISOAP No. 39, containing Ichthamol 5%, Ac. Salicyl 2½%, recommended in Acne Rosacea.

MEDISOAP No. 15, containing Ichthamol 5%, Pix Liquida 5%, is another popular formula.

For further particulars see *"Prescriber's Index."* *(free on request).*

HORLICK'S MALTED MILK

is a modified milk food with a fat content protected by the valuable mixed sugars—lactose, maltose, and dextrin. It forms a balanced diet which is easily digested and assimilated.

It is a valuable aid to the physician in the dietetic treatment of many diseases associated with childhood. Marked success has attended its use in digestive disturbances, epidemic diarrhoea, and in infective and respiratory conditions with which acidosis is associated.

During recent years acidosis has attracted much attention, and it is now recognized that many children who exhibit vague symptoms of ill-health, are debilitated, or who are liable to bilious attacks, suffer from it in some degree. In many cases the condition is due to an intolerance for fat, and is made worse by efforts directed towards improvement by feeding-up the patient with unmodified cow's milk, extra cream, and fatty foods.

To prescribe HORLICK'S for these children is to know that they will speedily regain full health and vitality.

MANGANESE BUTYRATE B.D.H.

In acute Staphylococcic and Streptococcic Infections

Manganese Butyrate B.D.H. is particularly useful for combating staphylococcic and streptococcic infections, and it is recommended for use in many septic conditions before resort is made to incision.

The following are typical case reports:—

Case 1—"A baby, four months old, suffered from mastitis (pus formation). The abscess resisted all local treatment and continued to fill. A few days after a 0.25 c.c. injection of Manganese Butyrate the abscess cleared."

Case 2—"A septic stye in the eye, with promise of running a bad course, after one injection of Manganese Butyrate showed a marked improvement, and a second injection given later so improved it as to make it difficult to observe any difference in the eyes."

Case 3—"A child with large hard adenitis under the chin. In forty-eight hours it came to a head and discharged very freely and cleared up very quickly also.

THE WEAKEST SYSTEM RESPONDS AT ONCE

to these energizing essences

The wonderful stimulating and restorative properties of Brand's Essences of Beef or Chicken have given them the place of first rank among invalid foods.

For over a century doctors have relied on them in their treatment of illnesses because they stimulate, build up energy, and restore appetite. As a preliminary to solid diet they are unparalleled.

Scientific tests have shown that Brand's Essences of Beef or Chicken can be assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of residue. Easy to swallow, they are entirely suave and non-irritating.

Hygienically prepared by an exclusive process from the finest freshly killed English meats, the pure juices are drained out and conserved as a delicious amber-coloured essence. No preservatives or colouring matter are used.

Brand's Essences of Beef or Chicken have been found to be indispensable in all disorders associated with pyrexia, in cases of intestinal disturbances and before and after operations. Patients recovering from a long illness and suffering from anorexia find them particularly beneficial.

Ask for samples to-day. They will be gladly sent you on receipt of a professional card. Dept. F33, Brand and Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES OF BEEF OR CHICKEN

3168

For the Treatment of Haemorrhoids

SANUSIN SEMPULES

The sempule is an improved form of suppository, specially moulded so that a small portion remains external to the anal sphincter after insertion; the medicament is thus retained at the seat of the disorder until completely melted, thereby assuring its prolonged application and greater absorption. Herein lies its distinct superiority to the usual type of suppository which does not remain in situ, but which passes on and melts in the rectum—thus failing to produce the local effect desired in the treatment of haemorrhoids.

Sanusin Sempules contain resorcin, boric acid, balsam of Peru, zinc and bismuth carbonate—a combination of substances which has great antiseptic and healing power.

Sanusin Sempules have been found effective in many cases which have resisted other methods of treatment.

Local Anæsthesia in Surgical Practice

CLEFT PALATE.

Typical Case.

E. M., aged 25 years.

Diagnosis: Cleft palate.

Operation: Plastic repair.

Anaesthesia: Novocain-Adrenaline solution.

Operation: Nerves were blocked with a 2 per cent. Novocain-Adrenaline solution, 30 c.c. in all being used. In addition to the nerve block an effort was made to separate the soft tissues from the bone by the "blowing-off" process. This was signally successful; the subsequent raising of the mucoperiosteum being greatly facilitated by this preliminary manœuvre. The palate united completely with the exception of an opening the size of a lead-pencil at the mid-point. This opening was later closed after making a local infiltration with Novocain-Adrenaline solution.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Digestibility

*(1) The Fat Content

FACTS ABOUT
LACTOGEN

The ease with which maternal milk can be digested by the infant is partly due to the distribution of the fat as numerous small globules. With an equivalent quantity of fat the globules in cows' milk are many times larger and correspondingly fewer in number. Digestion is thus retarded, since the surface offered to digestive action is considerably diminished. The cream-enriched milk used in the preparation of Lactogen is subjected to a special emulsifying process before drying. This reduces the large fat globules to a state of fine division—increasing by a hundred times the initial surface area. Lactogen, furnishing a fat allowance corresponding to that of the natural diet, can therefore be digested just as easily—even by the most delicate infant.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

Free Samples

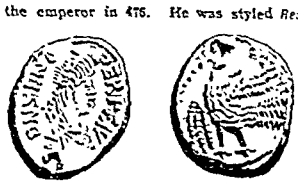
COIN OF ODOVACAR OR ODOACER, WHO MADE ITALY A TEUTONIC KINGDOM, WHICH IT REMAINED FOR SEVERAL CENTURIES.—The extinction of the Roman empire in the West and the rise of the Teutons was marked by the establishment in Italy of Odovacar, the first of a succession of "barbarian" rulers of that country. He was the military leader of the Heruli tribe, under whom they overthrew the emperor in 476. He was styled *Rex Herulorum*, and reigned in Italy from 476 to 493. *It is interesting to find* that he made use, as fully as possible, of the old Roman administrative system; a large new racial element was introduced (for Odovacar's *soldiers were settled upon the land, occupying one-third of it*) with but little disturbance of legal and social conditions. He was acknowledged by the Senate and was addressed by his Roman subjects as *"dominus noster"*; he never attempted to assume the imperial title and seems to have sent the insignia of this office to the Eastern Roman emperor, Zeno, at Byzantium, with whom his relations were friendly. He allowed his subjects religious liberty, a rare tolerance in those days.



DATE: A.D. 476–493 (Odovacar, king of Italy)

COPYRIGHT

'Euvalerol' Elixirs

For the Treatment of Nervous Disorders

THE "Euvalerol" Elixirs are prepared from fresh valerian root by a special process which, while ensuring the retention of the active principles contained in the volatile oil of valerian, eliminates the objectionable odour which ordinary valerian products have.

"Euvalerol" Elixir A
contains the odourless preparation of valerian in Aromatic Elixir. Each fluid ounce is equivalent to approximately one fluid drachm of Tinct. Valer. Ammon., B.P.

"Euvalerol" Elixir B
is "Euvalerol" Elixir A with the addition of **phenylbarbitone gr. ¼** to each fluid drachm, and with a lighter tint, for ease of identification.

"Euvalerol" Elixir C
is "Euvalerol" Elixir A with **ammonium bromide gr. 30, strontium bromide gr. 15,** also a small amount of **sal volatile** in each fluid ounce. It has a darker tint than the other two "Euvalerol" Elixirs.

For Prescribing: 4 oz. and 8 oz. bottles
For Dispensing: 40 oz. and 80 oz. bottles

Descriptive Literature will be sent post free to members of the Medical Profession.

Remarks ON OBSTETRIC SHOCK*

BY

MILES H. PHILLIPS, M.B., B.S., F.R.C.S.

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF SHEFFIELD

Although an alarming case, and especially a fatal case, of shock following a labour is a rare experience for any individual medical practitioner, a considerable number do occur throughout the country. This is established by the investigations which the Departmental Committee on Maternal Mortality and Morbidity has been able to carry out. Presumably a larger number are saved by suitable treatment at the cost of grave anxiety to the doctor in charge. After a careful study of such cases, especially of the predisposing conditions which play a great part in the causation of the shock, and also of the earliest signs of impending shock, I feel convinced that the subject is one well worthy of close attention.

In some cases of shock the cause may be at once obvious—for example, rupture or acute inversion of the uterus; in others, such as a prolonged and difficult forceps delivery, resulting in a severe laceration of the pelvic floor and followed perhaps by post-partum haemorrhage, it is not surprising to find the patient in a collapsed condition. But there is another type, more difficult to detect, in which the patient's condition is at first not alarming—no worse than one would expect considering that the labour had been rather long. "It was rather a tight fit"; there was somewhat more than the usual amount of bleeding, and she had needed stitches. She looks chilled, and the pulse rate is over a hundred; warm blankets and a rectal saline should put her right; they may, but in certain distressing cases the doctor is called back in two or three hours to find the patient desperately ill, and indeed she dies. The primary shock had not in itself given a warning of the impending and insidious secondary phase.

After all, obstetric shock is just the same thing as traumatic or surgical shock. It has the same causes, initiating and predisposing, and must be treated on the same principles. The distinction into primary and secondary phases must be ever in our minds in order that by recognition and prompt thorough treatment of the primary stage, the secondary—the fatal secondary—may be staved off. To anticipate my main conclusions: the blood pressure must be taken and used as a guide in all cases; the depleted plasma of the circulation must be replenished quickly and effectively by the most suitable fluid available, preferably by the injection of gum saline solution intravenously, though intravenous or even subcutaneous normal saline will always do good even if of short duration—it may keep the patient going until more effective fluids are available.

PRIMARY AND SECONDARY SHOCK

It is here necessary to give a short description of the modern conception of traumatic shock. My account is largely based on Cannon's work on the subject.[1] Clinical as well as experimental observations distinguish two stages—primary and secondary.

Early or primary shock is due to afferent impulses causing reflex vaso-dilatation and a consequent marked fall of blood pressure. For long it was thought that the blood vessels of the abdominal viscera were chiefly involved, but it is now recognized that it is in the reflexly dilated capillaries of the skeletal muscles that the blood is dammed up—for the time being, lost to the circulation. The consequent diminished blood supply to the brain will result in faintness and even in loss of consciousness.

The capacity of the dilated capillaries of the voluntary muscles must be enormous. Professor Krogh[2] of Copenhagen, the recognized authority on the subject, states that the capillaries of a man's muscles put end to end would measure 100,000 kilometres, or two and a half times round the globe; their total surface would extend to 6,300 square metres, which I believe is about an acre and a half.

This is no doubt the true explanation of both obstetric and surgical shock, but in the obstetric cases there is also another factor in the more or less sudden lowering of the intra-abdominal blood pressure which follows the emptying of the uterus. In fact, this alone would seem sufficient to explain the phenomena so commonly seen after delivery—the faintness for which we withdraw the pillow beneath the patient's head, the shivering bout, which is probably a reflex from the skin deprived of its full supply of blood. The famous experiments on rabbits strongly support this supposition. A hutch rabbit held up by its ears will die because its disused flabby abdominal muscles cannot support the abdominal blood vessels. The wild rabbit so treated is unaffected; so is the hutch rabbit with a tight binder around its abdomen. Acting on this theory, I always insist on a tight abdominal binder being used as soon after the delivery as possible. In fact, it is only in the first few hours that a binder is of any use at all. With prompt and adequate treatment recovery will gradually take place from this primary shock; otherwise it may merge into the succeeding phase.

Delayed or secondary shock may set in after a latent period, during which nothing obviously abnormal may be noted unless a routine blood pressure reading has been taken. (In the obstetric case it is the downward tendency of the systolic blood pressure which gives the first premonitory warning of impending shock.)

Experiments—especially those of Cannon of Harvard University, in which the effect of crushing the skeletal muscles of animals has been studied—strongly suggest that traumatic shock is caused by some poisonous substance which is liberated from the damaged tissues and causes widespread relaxation of the capillaries. This takes some little time to develop, though it began in twenty minutes in some of the experiments and was well marked in half an hour. Its effect, of course, is to add to the stagnation of blood in the already dilated capillaries of the muscles. The poisonous substance liberated is either histamine or something closely allied and resembling it in action. It is present in all tissues and is readily liberated as a result of even trivial injuries. Besides causing dilatation of the capillaries, the toxic body, whatever its exact nature, also increases the permeability of the capillary walls, and so produces a reduction of blood volume by escape of plasma into the tissues. The amount of blood plasma circulating to the other parts of the body, particularly to the vital centres of the brain, is gravely diminished; this is the essential feature in the modern conception of shock.

The experimental evidence of this toxic explanation of secondary shock was strongly supported by clinical observations during the war. A French surgeon, Professor Quénu of Paris, demonstrated that extensive wounds of muscles were particularly apt to cause profound shock; he also established the view that anything which favours absorption at the region of injury is favourable to the development of shock, and that shock is most severe when the region of damage communicates with the exterior by only a small opening.

By applying these observations to obstetric practice I would venture to suggest that the unexpected secondary

* A paper read before the Sheffield Medico-Chirurgical Society on March 18th, 1931.

phase of obstetric shock may be due to extensive lacerations of the large muscles of the pelvic floor, the levatores ani, especially when such injuries are not accompanied by deep tears of the perineal body and vagina sufficient to expose the lacerated muscles. There is much clinical evidence for such a view. Routine early or late postnatal examination not seldom detects grave damage of the large pelvic floor muscles. The gynaecologist in operating for genital prolapse obtains ocular demonstration of these injuries. During delivery of the head with forceps probably all obstetricians have felt at one time or another "something give way" before or even without any serious tear of the perineal body. (This possibility might be investigated by those making post-mortem examinations in cases of obstetric shock.)

SIGNS OF SHOCK

In marked cases the patient lies very still, as if felled, paying no attention to what is going on around her. Anxiety has changed to mental dullness. The skin and mucous membranes are cold, grey, or cyanotic. The pulse is almost imperceptible, and, as a rule, very rapid. Respiration is shallow and quickened, the temperature subnormal, and the arterial blood pressure is low, perhaps unrecordable. The condition must be contrasted with that produced by haemorrhage alone. Here the patient is mentally alert and acutely anxious, tossing about or struggling to sit up as she gasps for air.

CAUSATION

From the point of view of treatment, and especially of preventive treatment, it is necessary to elaborate the question of causation. Besides the essential initiating causes produced by the original trauma—the primary reflex vaso-dilatation and the secondary toxic poisoning—there are other predisposing conditions or complicating factors. These are all present in varying degrees in the obstetric case. Without attempting to give them in order of importance, they are:

1. Bodily fatigue from prolonged muscular exertion.
2. Cold from exposure.
3. Deprivation of food and water.
4. Sweating
5. Haemorrhage.
6. Anaesthetics.
7. Toxaemia of pregnancy.
8. Infection.
9. Emotion.

Of these I wish at the moment to draw particular attention to two only.

Haemorrhage

This is often a considerable factor, yet of itself it does not give rise to a prolonged permanent fall of blood pressure unless more than 25 per cent. of the body blood is lost. (A woman of 10 stone possesses about eight pints of blood.) Combined with injury it naturally aggravates shock, and therefore every effort must be made to prevent further loss of blood.

Anaesthesia

The type of general anaesthetic used is of prime importance. H. H. Dale[1] has shown experimentally that both chloroform and ether, but not nitrous oxide with oxygen, sensitize the capillaries to the action of histamine, so that in unanaesthetized animals about ten times the dose of the drug is needed to produce a depression of blood pressure equivalent to that in the animal anaesthetized by chloroform or by ether. This has been confirmed by other observers, and Cannon himself says:

"The explanation of the difference between nitrous oxide and oxygen on the one hand, and such anaesthetics as ether and chloroform on the other, in their effects on the blood pressure in shock, has not been fully accounted for. The practical matter, however, is that the patient in shock may be anaesthetized with nitrous oxide and oxygen and suffer no appreciable drop in blood pressure, whereas with ether or chloroform the drop is likely to be considerable and possibly highly dangerous."

Consideration of the other predisposing or complicating factors may be most usefully left to the section on preventive treatment. Cannon lays great stress on sustaining factors which result from the shock itself. These are the lowered metabolism resulting from the fall of blood pressure, the diminished heat production, the defective oxygen supply of all the tissues and of the nervous tissues in particular, and the damage to the walls of the capillaries. He says:

"These injuries to the elements which are essential to the maintenance of an efficient circulation, continue the state of shock which has been originated by other factors and may lower still further the already low arterial pressure."

A series of vicious circles is set up which lead to a depression of the circulation so profound that it cannot be restored, and the patient dies.

TREATMENT OF SHOCK

It is therefore of great importance that the treatment of the original condition should be prompt and adequate. Any further loss of blood must be prevented as far as possible. Body heat must be restored by the means most easily available, care being taken to avoid overheating and consequent sweating. In the less severe cases hot drinks are by far the best method of warming, as all the heat passes to the body itself. Pain, anxiety, and restlessness should be relieved by the injection of morphine, which should be given in an amount sufficient to make the patient quiet and comfortable.

In secondary shock, where blood is not stagnating in the large veins, there is no benefit to be gained by raising the foot of the bed. In the primary condition, however, particularly in obstetric cases with the special tendency to lowering of the intra-abdominal pressure, raising the foot of the bed will almost certainly improve the blood supply to the brain.

Above all, every precaution must be taken to avoid the development of secondary shock. This essentially consists in taking measures to raise the blood pressure. It is of the greatest importance to remember that it is often only by recording the blood pressure that the attendant is brought to realize the seriousness of the state of the patient, the great care that must be taken to prevent further exposure to the conditions which produce shock, and the necessity of employing really effective methods of increasing the volume of blood in circulation.

With the systolic pressure below 100 no operative treatment should be carried out, unless it is absolutely necessary in order to stop the loss of blood. Even then, the only safe anaesthetic to use, as we have already seen, is nitrous oxide and oxygen. Most certainly neither chloroform nor ether should be given for any operative treatment which is not essential at the moment. Here I particularly refer to the suturing of the torn perineum. The dictum "immediate repair of all tears" should always be qualified by excluding the cases in which the patient is shocked. Want of appreciation of this danger is a definite cause of maternal deaths. There is really no urgent necessity to suture immediately a perineal wound. Just as good a result can be obtained by repairing it a few hours later, when the patient has recovered from the shock. Indeed, often a better result can be assured, for time is given to provide assistance, good light, etc. Again, it is sometimes better surgical practice to leave the wound open. I refer to those cases (potentially infected, and often the very cases in which shock is pronounced) where

the labour has been greatly prolonged, in circumstances in which there is considerable liability to bacterial infection. Twenty years ago[5] I produced evidence to show the grave danger to life caused by replacing the inverted uterus when the patient is in a condition of shock. Since then I have come to realize that even the repair of a torn perineum may take away the patient's chance of recovery.

Restoration of Volume of Blood Plasma

All the above procedures are easily carried out. The most important measure, however—namely, that necessary to increase the amount of fluid in the circulation—requires forethought and gives more trouble. Every obstetrician should always be provided with the simple apparatus needed to give at least a subcutaneous saline. Ideally he ought to be prepared to give an intravenous infusion of saline or other more effective fluid. For well-known reasons gum saline solution is definitely more beneficial—more lasting in its effects, especially in the more severe cases—than simple saline. It is nowadays so carefully prepared and conveniently put up by the big chemical firms that there is no excuse for not having it at hand. Warmed to a little above body temperature, it must be injected slowly, at low pressure, into the vein (the more *profound and prolonged the shock, the more slowly ; in* one's anxiety this is not an easy rule to remember). About 500 to 750 c.cm. (a pint more or less) is enough for a first injection ; but another may have to be given. To ensure safety forty to sixty minutes are required for this procedure.

A blood transfusion is even more effective, especially in cases of severe haemorrhage ; in modern hospitals this can usually be carried out within an hour or two. But while waiting for the blood—and this is a point which I particularly wish to emphasize—precious time must not be wasted. The simpler means at hand must be employed. It must not be forgotten that many a life was saved by simple saline solution long before blood transfusion was in vogue. All experienced surgeons can testify to the value of normal saline infusion, especially in cases of haemorrhage.[6] In studying reports of fatal obstetric cases from all over the country, one is dismally impressed by the repeated statement that blood transfusion was considered necessary but was not available, and yet in many of these cases either no attempt at all was made to give any form of fluid, or nothing more than a rectal saline was used. It is very doubtful if this is absorbed at all, or at least rapidly enough, in any but slight cases of shock. A pint or two of normal saline into the large cellular space of the axilla may suffice to restore a mild case, or maintain the serious one until blood is available.

PREVENTION OF SHOCK

This is a much more satisfying procedure for everyone concerned. I have already given a list of predisposing causes, and it will be easiest to indicate the precautions required under those headings.

Bodily Fatigue from Prolonged Muscular Exertion

The amount of muscular exertion involved in labour is, of course, very variable. It should not impose too great a strain on the woman who, by virtue of proper ante-natal management, is in good physical and mental condition at the onset of labour. This essentially involves care in diet, daily exercise, and sound sleep at night. Special attention should be paid to the last point at the end of the pregnancy; if necessary a sleeping draught should be given. During the actual labour, if it be at all prolonged, the necessity for sleep, or at least oblivion to the passage of time, is of still greater importance. The prevention of undue prolongation of the labour requires fine obstetrical discrimination. It is unkind to mother and child to allow the second stage to be unnecessarily protracted—the head in an occipito-posterior position, for instance, pounding on the rigid perineum hour after hour. But it is dangerous to both mother and child, especially from the point of view of shock, to shorten, or to endeavour to shorten, the labour by the premature use of forceps. This misuse of a valuable instrument is too common a cause of the condition we are considering, especially in the primigravida. Extensive trauma is often the result.

Now the stress in labour is much more on the nervous than on the muscular system of the patient ; this must be our guide in seeking to give relief to the actual pain and mental strain. More and more the modern woman demands this relief. What is the best means? Some years ago I read a paper to this society on this question, largely in praise of chloral hydrate, a most valuable drug in some cases of delay from inertia. But for the relief of actual pain I have been entirely converted in the last eighteen months to the use of scopolamine, without any morphine, in the large doses recommended by Dr. David Jennings.[7] When the pains begin to distress the patient, whether in the first or second stage of labour, one-hundredth of a grain is given ; the dose is repeated in half an hour, and again at the end of the next half-hour if it be required. After that the same dose is given at about two-hourly intervals. In most cases only one, two, or three doses are necessary, but I have known as many as six to be given in the course of ten hours. In my experience no harmful effects have occurred ; uterine contractions are certainly not diminished by it, as they may be with morphine. I have never seen the somnolent baby that used to bother me occasionally when morphine was given with small doses of scopolamine. The feeling of well-being, mental and physical, has long been recognized after "twilight sleep." It is most striking after these larger doses. But it is as a preventive of obstetric shock that this method of scopolamine treatment appeals to me.

For some two years the blood pressure, during and after labour, has been recorded in my private cases, and in an increasing number of cases at the Jessop Hospital for Women. The senior resident officers, Mr. Alan Fawcett, and, during the last twelve months, Dr. E. ap I. Rosser, have put themselves to much trouble to make these observations, and I am greatly indebted to them. I have no doubt that the recording of blood pressure will soon be generally recognized as a routine requirement. It has been carried out in all cases at the Jessop Hospital during the last nine months. Sisters in the labour ward can be trained to take reliable readings.

On studying the blood pressure records, taken during the various stages of labour and immediately after, in scores of cases during the last fifteen months, I have been greatly impressed by the fact that the fall of blood pressure has been less when scopolamine is used. In fact, in many cases there is no fall at all, and when anaesthesia is induced during the actual delivery by means of nitrous oxide and oxygen, we have records of even a rise in the systolic pressure. This combination of scopolamine analgesia and gas anaesthesia is the most beneficial advance in the management of labour which I have witnessed. Other drugs are being tested, such as avertin and amytal, but of their value I have no experience. I believe that the solution of the problem of relief of pain in labour will be found in the use of such drugs as scopolamine, rather than in the widespread administration of general anaesthetics such as chloroform.

Cold from Exposure.—As a rule, precautions have been taken to eliminate this factor by proper warming of the room. However, I can recall several instances in which

I have found an emergency case chilled to the marrow in an ice-cold bedroom. In one Derbyshire farmhouse it took two hours to warm up a patient sufficiently to warrant her removal by ambulance. There is also the unavoidable exposure during instrumental delivery and perineal repair. A perineal cloth is some protection, and for years I have always taken a thick pair of stockings, such as are used in operating theatres, to emergency confinements.

Deprivation of Food and Water.—In addition to the usual fluid diet, the free drinking of glucose solution (one pound to a quart of water) is helpful; it is better than the heavily sugared tea with which we plied our district patients in my student days.

Haemorrhage.—To prevent undue loss of blood is a fundamental rule of midwifery. But the average pregnant woman can stand and quickly recover from a haemorrhage considerably more severe than that seen in normal labour. Everyone has observed this time and again. There is just the danger that such experiences may lead to a forgetfulness of the extra care required to control the loss of blood in those cases in which other factors predisposing to shock are present. I need only refer to the necessity for additional care in managing the third stage of labour in cases of placenta praevia. There is grave danger in allowing a trickle of blood to continue during that stage. One must remember that the placenta is already separated to some extent: it must be expressed or removed should a trickle commence.

The prophylactic use of normal saline, gum saline, or even blood transfusion during the course of labour in cases of ante-partum haemorrhage is of great importance in preventing the onset of shock which is so apt to occur after the delivery. Pituitary extract is useful in diminishing the loss of blood by its action on the uterine muscle, and by virtue of its pressor factor it helps to maintain or even raise the systolic blood pressure. In recent years pituitary extract has been standardized, and purified, by washing with alcohol, whereby the "histamine"-like impurity, a product of protein decomposition, has been removed. The danger of overdosage, with consequent syncope due to spasm of the coronary arteries, has thus been greatly lessened, and the risk of actually injecting "histamine" is eliminated. I have seen nothing but good result from the injection of five to ten units of the modern preparation in such cases as we are now considering.

General Anaesthesia.—I have already referred to the grave danger caused by the use of chloroform or ether in the presence of shock. Prolonged use of either of these drugs in labour predisposes to the onset of shock. This applies particularly to chloroform, and especially to the repeated use of chloroform in those obstetric cases—not so very uncommon—in which an anaesthetic is required on two or more occasions during a labour—for example, for the induction of labour, or for a thorough examination in the earlier stages, and later on for the actual delivery or for repair of lacerations. Chloroform is a very useful and convenient drug in midwifery, but it should be used chiefly to relieve the pain caused by the actual birth of the child.

Ether can be given with greater safety for more prolonged periods, but both drugs definitely diminish the activity of the uterine muscle and tend to lower the blood pressure. In all these respects they are greatly inferior to nitrous oxide and oxygen, which, properly given, is not toxic and does not in the slightest degree lessen uterine activity; it often appears to intensify it. Its value is so great that I strongly hold that all maternity hospitals should be provided with an efficient apparatus for its administration. It is nowhere seen to greater advantage than in those cases of "failed forceps" which often show considerable shock on admission to hospital, from trauma and either exposure to prolonged chloroform or the absence of any anaesthetic at all. Annual reports of maternity hospitals nearly always record the death from shock of one or more of these patients. I believe many of them could be saved by the use of gas and oxygen when an anaesthetic is required. McKesson's smaller apparatus, specially devised for obstetric work, is wonderfully efficient and conveniently portable.

Toxaemia.—The woman suffering from toxaemia of pregnancy, especially the nephritic type, is markedly susceptible to the influences which favour shock. Induction of labour must therefore not be delayed if the toxic state is increasing. Methods of delivery involving the least trauma must be chosen. Chloroform should never be given, and ether is not much less harmful. Gas and oxygen is again the best anaesthetic. Glucose should be given by the mouth or even intravenously in severe cases.

Infection will add to the tissue poisons causing shock. It may occur during a prolonged labour, and, if suspected, it is advisable to leave open any perineal or vaginal wound, applying to it a sterile saline or glycerin dressing.

Emotion

This is a factor which is not often predominant, though it may well play a part more often than we realize. In analysing the causes of twenty-six maternal deaths which occurred in 9,468 deliveries (giving the low rate of 2.7 per 1,000) at the Royal Free Hospital, Dame Louise McIlroy[1] attributed six deaths to obstetric shock and four to shock from haemorrhage. She expressed the opinion that "fear, anxiety, and intense suffering during labour are predisposing factors, and that haemorrhage is not always sufficient to account for the collapse, and sometimes death, which occurs after a long painful labour."

We have already considered the use of drugs to relieve fear and anxiety, and to prevent intense suffering, but we must also remember the necessity of recognizing and protecting those patients who are unusually susceptible to emotional shock—by no means an easy matter. Perhaps I can best help by giving three examples. The first is taken from the Bible.*

"And his daughter in law, Phinehas' wife, was with child, near to be delivered: and when she heard the tidings that the ark of God was taken, and that her father in law and her husband were dead, she bowed herself and travailed; for her pains came upon her.

"And about the time of her death the women that stood by her said unto her, Fear not; for thou hast born a son. But she answered not, neither did she regard it."

Ill tidings should not be conveyed to a woman in labour. When a stillbirth occurs it is wise to induce, by means of morphine, a long sleep before the mother is told of her misfortune. Whitridge Williams, in his splendid textbook *Obstetrics*, records a case of emotional collapse, which I transcribe in full. In the section on sudden death during or after labour and under the heading "Profound mental depression" he tells this story.

"In rare instances the only apparent explanation for death, or for a profound collapse which eventuates in recovery, is to be found in the mental condition of the patient, since the most careful examination, both at the bedside and at autopsy, may fail to reveal the slightest abnormality.

"I recall a case in my own practice which apparently belongs in this category. The patient, who was unhappily married, had already passed through two difficult labours. When I saw her, in the latter part of the first stage of her third labour, she was about the room. Just before going to bed at the beginning of the second stage she asked the nurse and me to witness her will, as she said she felt sure she would not survive. The labour was rapid and uneventful, the placenta coming away spontaneously. An hour later, on approaching the bed to take leave of the patient, I was struck with her haggard appearance. Fearing the possibility of

* 1 Samuel, iv, 19, 20.

concealed haemorrhage, I at once applied my hand over the uterus and found it tightly contracted, while the pulse was of excellent quality. Without any apparent reason, and in spite of energetic stimulation, the patient grew slowly worse, the pulse becoming rapid and weak, the eyes sinking back in their sockets, and the face assuming a drawn and Hippocratic expression.

"Thorough examination failed to reveal the slightest cause for the condition. The hand introduced into the uterus could find no trace of rupture. Eight hours after delivery I requested a colleague to see her in consultation, but he also was unable to offer any explanation. It then occurred to me that the condition might possibly be the result of her morbid forebodings, and acting upon that supposition I administered a large dose of morphine hypodermically, which was promptly followed by sound sleep, a marked improvement in the character of the pulse, and some rapid change for the better in the general appearance. Upon awakening a few hours later the patient felt very comfortable and made an uninterrupted recovery."

From my own experience I can record a case which had a tragic ending. These are my notes.

M. W., aged 29, primipara. On April 25th, 1925, attended by her family doctor, a careful and experienced obstetrician. I was called in after the second stage of labour as the patient had collapsed. Labour, expected on the 27th, started on the 22nd. Poor pains, on the 23rd and 24th, were treated with morphine, hyoscine, and chloral. The membranes ruptured on the 25th at 9 a.m. The cervix was then fully dilated and quite effaced. At 11 a.m. 1/2 c.cm. of pituitrin was given. The feeble contractions increased slightly, but were not efficient. About 12 o'clock low forceps were applied under light chloroform anaesthesia induced by the doctor himself. The pelvic floor was very rigid, and twenty minutes were occupied in extracting the child. The patient collapsed very shortly afterwards. There was no haemorrhage, and only a slight tear of the perineal body. As there was no obvious cause for the collapse, and as the placenta had not come away, the doctor explored the vagina and cervix with his hand. He could feel that the placenta was still in the uterus, but, the patient's condition being very serious, he considered it unwise and probably unnecessary to remove it. He sent for assistance and started a submammary infusion of saline.

I arrived at 1 p.m., less than an hour after the delivery. The patient was then very pale, pulseless at the wrist, but not at all restless. The uterus was as high as the umbilicus, not relaxed, but contracting only slightly and at long intervals. There was no bleeding. She was at once given 1/2 c.cm. of omnopon, and glucose was added to the saline. She rallied slowly. By 4 p.m. her colour had returned, and the pulse was countable at the wrist—120, very small. At 7 p.m. the pulse was still 120, still very small, and the patient was sleeping. The condition of the uterus was unchanged. At 10 p.m. the doctor injected ergotamine hypodermically, as a "safeguard" for the night.

I saw her again the next morning at 11 o'clock; she had had a restless night and had passed two very small clots, without pain. The temperature was 98.4° F.; it had been up to 99° F. Her condition was much better. Her colour had returned and she talked freely. There was no abdominal pain nor rigidity. The uterus was unchanged. Before considering the question of removal of the placenta, we decided to move the patient into hospital (her mother had been taken to hospital for removal of adherent placenta after the patient's own birth). The patient readily agreed, but while talking quite cheerfully about the necessary arrangements her face suddenly set, her eyes stared (we thought a fit was impending), and she died in two minutes or less. Traction on the tongue, artificial respiration, strychnine injected hypodermically and into the heart, all failed to revive her.

Afterwards I inspected the vagina and cervix, but found only a moderate tear of the perineal body. I passed my hand into the uterus, but found no rupture. The placenta peeled off with no unusual difficulty. The uterine wall was thin and relaxed. There was no sensation of free fluid in the pouch of Douglas. The ultimate diagnosis was death from emotional shock.

The patient was of gipsy type, very deeply pigmented, and she was said by her father to be of a very emotional temperament. I have seen the statement made that darkly pigmented people are specially vulnerable to shock, whether physical or mental. Unfortunately no record of the blood pressure was taken, and no post-mortem examination of the pelvic floor muscles was made. It is noteworthy that the pelvic floor was described as being very rigid.

The exact cause of death in these cases is not known. Possibly direct cardiac inhibition occurs, but it has been shown experimentally by Cannon[9] and others that mental emotion will stimulate the suprarenal gland to excessive secretion. Now although adrenaline causes a prolonged vaso-constriction in skin vessels, it also produces "an increase in the volume of blood present in voluntary muscle and in the intestine." This has been demonstrated by Dr. G. A. Clark[10] in the physiological department of Sheffield University. We have seen that in traumatic shock the capillaries of muscles are relaxed. The effect of adrenaline either injected into or secreted by a patient already or recently the subject of traumatic shock, will therefore be harmful and possibly even fatal.

In the fatal case just described the placenta was retained. The relationship of shock to retention of the placenta is not quite clear. Personally I prefer the view that it is the shock which paralyses the uterus and causes retention of the placenta to that which holds that the adherent placenta promotes shock. Hence I agree that no attempt should be made to remove the placenta while the shock persists, unless, of course, partial separation leads to haemorrhage.

Finally, we are left with the prevention of emotional shock. This is too wide a subject to deal with here. It is perhaps best summed up in careful and considerate ante-natal care whereby the woman is helped to approach her confinement with a mind freed from anxiety and apprehension.

CEREBRAL CORTICAL STRUCTURE AND ITS RELATIONS TO MENTAL DISEASE

BY

R. J. A. BERRY, M.D., F.R.C.S., F.R.S.ED.

DIRECTOR OF MEDICAL SERVICES, STOKE PARK COLONY, BRISTOL; FORMERLY DEAN OF THE FACULTY OF MEDICINE AND PROFESSOR OF ANATOMY IN THE UNIVERSITY OF MELBOURNE

It seems reasonably safe to assume that the average medical man has little or no knowledge of the intricacies of the histological construction of the brain, now technically known as cyto-architectonics, or of the significance and practical utility of these developments in general and special practice. Yet English law may compel every medical man to certify, when necessary, cases of mental deficiency and mental disease; and the most recent Act of all implies a hope that more cures may be effected than heretofore. The profession is thus at a double disadvantage; and so it may be helpful if some brief account be given, as simply as possible, of recent advances in the study of brain structure and its relationship to mental disorder.

HISTOLOGICAL STRUCTURE

The microscopical study of the cells of the human brain is obviously attended by many and great technical difficulties, and is thus beyond the efforts of any but a limited and fortunate few. The work of these few has, however, had far-reaching results, culminating, at the moment, in the work of von Economo of Vienna, whose estimate of the number of brain cells in the normal healthy cerebral cortex is 14,000 millions, or some 5,000 millions more than the previous estimate of Donaldson of the Wistar Institute. These millions of brain cells are not arranged haphazard, as so many modern histological textbooks might lead one to suppose, but are definitely located in layers or laminae, of which English observers, like Bolton, Watson, Mott, and others, have recognized five.

It is perhaps not so well known as it might be that mammals are the only animal forms with a definite neo-pallial cerebral cortex or true end-brain. As the mammalian scale is ascended from the marsupials, through the anthropoids, up to man, this neo-pallial cerebral cortex becomes increasingly complex, culminating in the human brain. Originally a three-layered histological cortex, it becomes, in the higher anthropoids and man, a five-layered one. The successive results of these increments are to be seen in the enormous number of cells in the human brain, far exceeding that of any other mammal. In all mammals, however, these brain cells are arranged in a laminated manner, and the five of man were described and named by Shaw Bolton in 1912 as follows:

1. The outer fibre lamina.
2. The outer cell lamina, chiefly composed of pyramidal cells.
3. The middle cell lamina of granular or minute Golgi Type 2 cells.
4. The inner fibre lamina of axons.
5. The inner cell lamina of polymorphic cells.

From his investigations of the mammalian cerebral cortex Watson came to almost similar conclusions; but he pointed out that the mammalian neo-pallial cerebral cortex is primarily built up on an infragranular basis—that is, of layers lying within or internal to Bolton's third layer. He therefore simplified the nomenclature of the cerebral laminae by suggesting that the cortex should be considered as consisting of three main functional divisions: an internal infragranular cortex composed of polymorphic cells, an external supragranular cortex composed of pyramidal cells, with a third or granular layer between the other two, sharply delimiting the one from the other. There is no part of the body where structure so strictly accords with function as the nervous system, and that some significant functional importance attaches to these three contrasted forms of cells is certain. The views of Mott, Watson, and Bolton thereon are well known, and have been substantiated by others. I do not propose to give a detailed account of the work of these and other investigators, but to give a general introduction to von Economo's more recent researches.

Von Economo's smaller work, in 1929, on the cyto-architectonics of the human cerebral cortex is, in the main, confirmatory of the previous work of the English observers, though naturally differing in details. It extends the application of cortical cytology to other forms of mental disorder and disease, and indicates the different areas and laminae affected in some of the psychoses. Such a work is therefore of importance to the profession generally. Von Economo differs from English investigators inasmuch as he describes the cerebral cortex as a six-layered structure, not a five; and derives this extra layer by regarding the small pyramidal cells of the outermost part of Bolton's second layer as a separate and additional granular layer. These differences in arrangement and nomenclature will be rendered clear by *Fig. 1*, and by the comparative table below.

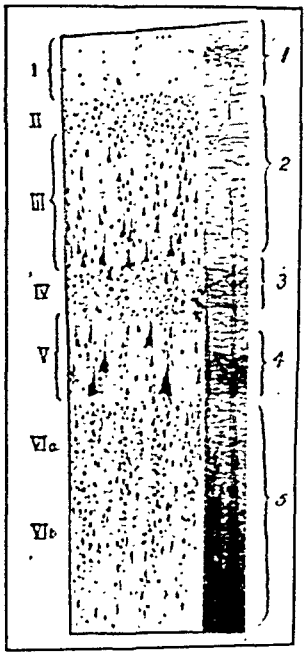

FIG. 1.—Layers of the cerebral cortex, as described and named by von Economo (on the left), and by Shaw Bolton (on the right).

BOLTON	WATSON	V. ECONOMO
1. Outer fibre lamina	Supragranular	I. Molecular layer
		II. External granular layer of fine pyramidal cells
2. Outer cell lamina, chiefly pyramidal cells		III. Pyramidal cell lamina of numerous large pyramidal cells
3. Middle cell lamina, chiefly minute granule cells of Golgi Type 2 variety	Granular	IV. Internal granular layer
4. Inner fibre lamina	Infragranular	V. Ganglionic layer, chiefly fine pyramidal cells
5. Inner cell lamina of polymorphic cells		VI. Layer of fusiform cells

It is to be specially noted that von Economo bases his classification of cortical laminae on cells only, whereas previous English investigators have included the well-defined strata of incoming or outgoing axons. Again, it will be observed that he separates off the small pyramidal cells forming the outermost part of Bolton's outer cell lamina as a separate layer of granules; a new point of some significance, as it means that the supragranular cortex is provided with a receptor layer as well as the older infragranular cortex. Against these minor differences is the major fact that all observers agree in regarding the human cerebral cortex as being a laminated structure with three main types of functional cells (pyramidal, granular, and polymorphic or *fusiform*), and that some functional significance attaches to each of these three principal strata. In von Economo's own and most recent words:

"In applying our present knowledge of cyto-architectonics to cerebral pathology, we must remember the following principles. The three chief forms of cells of the cortex (pyramidal, granule, and fusiform cells) are arranged in horizontal layers. The cortex consists of six such laminae, each of which has probably a certain function in the physiological activity of the grey matter."

LOCALIZATION OF FUNCTION

While it is undoubtedly true that certain portions of the cerebral cortex seem to specialize in particular functions, the conception of brain centres obtained from most textbooks of medicine is extremely misleading; and Broca's area, still unhappily described as the speech centre, forms an example of the persistence of an antiquated ignorance of cerebral function. Speech probably involves many portions of the cortex and myriads of cells in all layers. Notwithstanding this, certain portions of brain cortex do have specialized functions, as is proved by the findings of cyto-architectonics. Brodman, Campbell, Marinesco, Betz, and many others, divide the cortex, from the known arrangement of its cells, into as many as upwards of a hundred areas. It suffices to say, with von Economo, that there are at least five main structural types of cortical cell construction and lamination. Thus the area known generally as the Rolandic motor area is largely devoid of granule cells, which it does not need, because it is concerned with outgoing cerebral impulses. This comparative absence of granule cells enables us to recognize such portions of the cerebral cortex under the microscope with considerable facility, and von Economo calls these areas the agranular cortex. Areas, on the other hand, which are primarily concerned with the receipt of impulses from the chief exteroceptive senses, such as sight, hearing, taste, and touch in all its forms, will be particularly rich in granule cells, thus forming easily recognizable cortical areas, termed granular cortex. With these exceptions, the rest of the cortex is mainly made up of slight, but recognizable, variants of the five or six cellular layers. Correlating these facts with clinical conditions the Viennese and other Continental schools find that mental disorder is rarely associated with area lesions, but shows a predilection for certain laminae in one or other of the five types of cortex.

PATHOLOGICAL CHANGES

With the recognition of these five or six cortical layers of the brain there has subsequently accrued, especially as the result of English work, a considerable knowledge of their pathological alterations in association with certain mental disorders, especially in mental deficiency. It is now well established that mental deficiency results from a lack of development of the cells of either or both of the pyramidal and fusiform cortical layers, with a consequent diminution in their numbers, a disordered structural formation, a consequent microcephaly, and disordered psychological reactions to the environment best summed up, perhaps, by a single word, unsanity. Bolton, in his classic work on *The Brain in Health and Disease*, extended and applied our knowledge of cortical lamination to both the amentias and the dementias; and von Economo has been able to go even further in applying it to both psychology and psychiatry.

The agranular cortex, for example, shows no change in general paralysis, which chiefly affects some of the cell laminae in the anterior frontal lobe of the brain, parts of the parietal and temporal lobes, and certain other sites. According to Jakob, the majority of organic mental diseases do not attack areas of the brain, but show a widespread affection of the cortex with a predilection for certain regions. In demential psychotic disturbances of the personality, von Economo finds that the chief lesions are in the third cortical layer. On the other hand, those diseases which primarily affect the capacity for expression and motility show a particular affinity for the cells of the fifth and sixth layers. In those cases of senile dementia which show a striking extrapyramidal muscular rigidity, in addition to their psychic symptoms, von Economo finds a marked affection of the cells of the fifth and sixth laminae. In many other cases of dementia there is not only a destruction of cortical cells, but also a proliferation of the glial cells, as instanced by von Economo, and also found in a case now under examination from a recent post-mortem at Stoke Park Colony. Mental deficiency, on the other hand, does not result so much from a dissolution of brain cells, as from their inherent inability to develop, many of them remaining in the neuroblastic condition; and feeble-mindedness is, according to Hammarberg, a closely allied condition of inhibition of proper cell development.

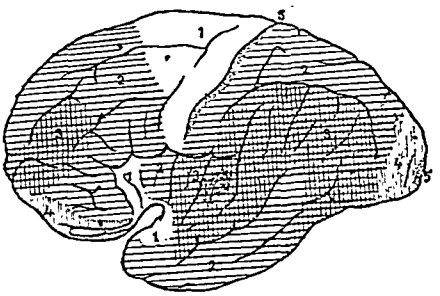

FIG. 2.—Cortical areas of von Economo. 1. Agranular cortex, chiefly confined to motor areas. 5. Granular cortex, chiefly found in sensory areas. 2. Frontal type. 3. Parietal type. 4. Polar type. Nos. 2 to 4 variants of the type illustrated in Fig. 1. No. 3 in the diagram corresponds to focal points of intelligence.

But cyto-architectonics is not of importance only to the psychiatrist. It promises results for the psychologist also, inasmuch as cellular studies of the cortex suggest that there are present richly receptive focal points of intelligence (von Economo) in both the prefrontal and parietal areas; but again the warning must be sounded that "for every kind of psychic expression the functioning of the entire cerebrum is necessary."

Thus does the apparently dullest and most forbidding of subjects, cyto-architectonics, hold out the greatest hope for the future of mental science in all its branches. And indeed it cannot now be long before the brain gives up the last of its secrets—the fashioning of mind out of the functions of neurones and their synapses.

ACIDOSIS AND SEBORRHOEA

BY

JOHN T. INGRAM, M.D., M.R.C.P.

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, GENERAL INFIRMARY, LEEDS; LECTURER ON DISEASES OF THE SKIN, UNIVERSITY OF LEEDS

AND

F. S. FOWWEATHER, M.Sc., M.D., D.P.H.

CHEMICAL PATHOLOGIST TO THE GENERAL INFIRMARY, LEEDS; READER IN CLINICAL CHEMICAL PATHOLOGY, UNIVERSITY OF LEEDS

The problem of seborrhoea is one of great importance and complexity. The minor manifestations of this disorder are so common as to be almost universal, while the major dermatoses of this group form a very large part of all skin cases seen in private and hospital practice. The subject is therefore one of interest to the general practitioner as well as to the dermatologist, and merits investigation from more than one point of view. MacLeod[1] and Dowling[2] have added much to our knowledge of the organisms concerned in the production of some of these disorders, but the seborrhoeic diathesis has received little attention, except from the clinician.

Three factors play a part in the production of most seborrhoeic affections—namely, a constitutional, an infective, and a precipitating factor. A brief explanation of each of these features is necessary.

THE CONSTITUTIONAL FACTOR

In a seborrhoeic subject the whole organism, as well as each separate organ or system, is abnormal to some appreciable extent. Outstanding among these variations is the functional instability of the skin, particularly with reference to its secretory functions, but also manifest in hypersensitivity to external or internal irritants, in vasomotor instability, and in diminished resistance to infection. In like manner the mucous membranes, especially those lining the mouth and upper respiratory passages, show secretory disturbances, diminished resistance to infection, and general hypersensitivity. There is commonly evidence of endocrine imbalance, a feature recognized by all authorities and sufficiently shown in the high incidence of seborrhoeic affections about the time of puberty and the menopause. Seborrhoeics are prone to dyspepsias and other functional disorders of the alimentary system. According to some authors they usually secrete a hyperacid urine[1]; if this is true, it may only be the result of some disorder of the secretory mechanism of the kidney. They are subject to vasomotor disturbances and to functional disorders of the cardio-vascular system. They appear to be more prone to the minor affections of the respiratory organs; and they are commonly the subject of nervous and emotional instability.

The seborrhoeic constitution, it would seem, can be summed up as one of general functional instability, and the question arises whether this feature is dependent upon a primary nervous instability, or upon endocrine imbalance, or whether the syndrome is the result of some unrecognized biochemical abnormality. The problem is probably most easily explained upon the basis of a primary nervous disorder; this is supported by the incidence of seborrhoea in the course of, and as the result of, epidemic encephalitis lethargica.[4] Whatever the basic factor may be, there can be no doubt that constitutional predisposition is the essential consideration in the elucidation of this group of disorders.

THE INFECTIVE FACTOR

The organisms chiefly concerned in provoking seborrhoeic manifestations—the *Staphylococcus epidermidis albus*, the seborrhoeic or acne bacillus, and (most important of all) the bottle bacillus or pityrosporon of Malassez, the nature of which has been recently demonstrated by MacLeod[1] and Dowling[2]—are harmless saprophytes on the normal skin, but may provoke inflammatory reactions in the skin of the seborrhoeic subject. These organisms assume chief importance in the minor manifestations of seborrhoea, as scurf of the scalp, simple pityriasis corporis, and, to some extent, in acne affections, all of which are readily amenable to treatment. The infective organisms of seborrhoea play only an insignificant part, however, in the grosser and more chronic seborrhoeic affections—chronic seborrhoeic dermatitis and eczema, gross acne and rosacea, which are most resistant to treatment and present the dermatologist with some of his most difficult problems.

THE PRECIPITATING FACTOR

Probably every seborrhoeic disorder is dependent at its onset on some precipitating cause acting upon the unstable constitution of the subject, and so reducing resistance to infection or disturbing functional activity of the skin. Such jars may take the form of infective or toxic injuries, physical or chemical trauma, occupational hazards, environmental changes, psychological disturbances, puberty, menopause—indeed, any change affecting the constitution as a whole. It is not our purpose to discuss further this aspect, but to confine ourselves to a consideration of the constitutional factor upon which seborrhoeic disorders must arise.

NATURE AND RESULTS OF INVESTIGATION

We proposed to investigate the acid-base balance in the blood of seborrhoeic subjects, hoping to find some clue as to the character of the constitutional disability we have described.

Sabouraud[3] in 1902 suggested that many seborrhoeics passed a hyperacid urine showing excess of chlorides and diminution of phosphates. In 1918 Barber and Semon,[4] from their study of a large number of cases of seborrhoea among soldiers on active service, reaffirmed this finding as regards hyperacidity, and from certain therapeutic investigations concluded that the "status seborrhoeicus"—as they described the constitutional dyscrasia in seborrhoeics—was essentially a state of relative acidosis. It is widely held that treatment by alkalis is constantly beneficial in seborrhoeic affections (an impression which one of us has not been able to confirm from the clinical point of view) and the finding of a state of relative acidosis in the blood would put such a line of treatment on a rational basis. It seemed to us, therefore, that it would be of some value to examine the blood in various types of seborrhoeic affection from this point of view. Our investigation covered a series of patients of all ages, suffering from various types of the more marked constitutional seborrhoeic disorders.

To say that an acidosis is present in any condition does not carry us much further towards a real understanding of that condition, unless we know something of the mechanism by which the acidosis is produced. Beyond stating that chemical examination of the urine never revealed the presence of diacetic acid or β-oxybutyric acid, Barber and Semon offer no further evidence as to the nature of the acidosis which they believed to be present. As we shall show later, hyperacidity of the urine does not necessarily mean that there is an increase in the total excretion of acid. Further, even when there is an increased excretion of acid, it is not absolutely necessary to conclude that an acidosis is present; for if we assume that, in consequence of some functional disturbance of the kidneys, these organs excrete more acid than normally, while the production of acid within the body remains at its usual level, the result would be a *relatively* increased balance of alkali within the body—that is, we should have an alkalosis. We are not aware that such an alkalosis has ever been described, but its occurrence in this way is conceivable. A similar explanation has been advanced for the alkalosis which sometimes occurs in association with pyloric stenosis—namely, that excessive loss of hydrochloric acid from the stomach, due to vomiting, is the cause of the increased alkali reserve.

Barber and Semon found confirmation of their views regarding the presence of acidosis in seborrhoeics, in the results of tests for alkaline tolerance. It was claimed that these tests showed markedly increased tolerance in the majority of cases. But tests for alkaline tolerance (for example, Sellard's test) are not entirely free from objection as tests for acidosis, and, moreover, in recent work it has been shown that the limits of alkaline tolerance in normal individuals are much wider than was originally supposed. Sellard put the upper limit of alkali tolerance at 5 grams of sodium bicarbonate, while, more recently, Hawk and Bergeim[7] put it at 30 grams.

EXAMINATION OF THE BLOOD

It seemed advisable to investigate acidosis in seborrhoeics having regard to the blood, rather than to the urine. In general, changes in the urine depend on and reflect changes occurring in the blood. An examination of the blood is therefore a more direct approach to the problem than an examination of the urine.

Acidosis is of two main types—namely, that concerned with volatile acid (that is, carbonic acid) and that con-

cerned with fixed acids. There is no reason whatever to assume that in seborrhoea we are dealing with the former type. On the contrary, it is to be inferred, from what has been written on the subject, that, in this condition, certain metabolic disturbances are supposed to be present which result in the production of fixed acids in increased amount, and these have to be dealt with by the blood and finally excreted in the urine. The first result of the pouring of increased amounts of fixed acids into the blood stream is the using up of increased amounts of the alkaline buffer salts (chiefly sodium bicarbonate) which are present in the blood to effect their neutralization; in short, a reduction of the alkali reserve of the blood. Changes in this alkali reserve are fairly well represented by changes in the sodium bicarbonate content, or of the carbon dioxide combining power. The determination of the latter is a fairly simple procedure, which is often employed in clinical investigations, and it is this determination which we have used in the present inquiry.

The normal range for the carbon dioxide combining power of the blood, as shown by Van Slyke, Stillman, and Cullen,[8] is from 53 to 77 c.cm. of CO_2 per 100 c.cm. of plasma. The results which we have obtained in 26 cases of seborrhoea may be grouped as follows:

CO_2 *combining power*: Over 70 c.cm. per 100 c.cm. of plasma, 4 cases; 65 to 70 c.cm., 9 cases; 60 to 65 c.cm., 7 cases; 55 to 60 c.cm., 4 cases; less than 55 c.cm., 2 cases. *The highest figure obtained was 77.7 c.cm., and the lowest 50.9 c.cm.*

It will thus be seen that of our 26 cases, 16 give results between 60 and 70 c.cm.—that is, they fall well within the normal range; 4 cases give values above 70 c.cm., and so approach the *upper normal limit—that is*, alkalosis—while 5 cases give results between 53 and 60 c.cm., and so approach the normal lower limit, or acidosis. Only 1 case gave a result (50.9 c.cm.) which can be considered as outside the normal range. The values obtained and the range shown are almost exactly what would be expected from a similar number of normal individuals. It is clear that, in our cases, there is no evidence whatever of any general tendency towards a depletion of the alkali reserve, and, so far as *the blood is concerned, there is no evidence of* acidosis. These results were not according to our expectations, and during the latter part of the investigation we decided to make examinations of the urine as well as of the blood.

EXAMINATION OF THE URINE

Acidity of the urine is only very roughly gauged by its action on any single indicator. The degree of acidity is most accurately ascertained by determining its *p*H; for practical purposes this can usually be obtained with sufficient accuracy by noting the action of the urine on a series of indicators, or on a composite indicator which shows a number of colour changes over a fairly wide range. But the degree of acidity of urine is not an indication of the actual amount of acid present, since it depends very largely on the amount of buffer substances (chiefly phosphates) present in the urine, and also on the nature of the acids, as well as their quantity. It is obvious that, *for the* purpose of investigating acidosis, the amount of acid excreted offers more information than the degree of acidity of the urine, and this is best obtained *by determining the* titration acidity of the urine—that is, the amount of standard alkali required to neutralize the urine (with phenolphthalein as indicator). The most useful value is that obtained from the twenty-four-hour specimen, but, *unless great care is taken in the* collection and preservation of the urine, very considerable error may be introduced, owing to the liability of the urine to undergo fermentation, with the production of ammonia. As most of our patients were out-patients, we felt it unwise, therefore, to consider the results on twenty-four-hour specimens, and contented ourselves with single specimens passed at the time the blood specimens were taken, and analysed immediately after being passed. All specimens were taken about four hours after the patient's last meal.

The normal values for the titration acidity of urine vary considerably; they usually lie between 10 and 40 c.cm. of decinormal sodium hydroxide per 100 c.cm. of urine. Very much larger values are frequently obtained in acidosis. The urine of 15 of our cases has been examined in this way, with the following results:

Less than 10 c.cm., 5 cases; from 10 to 40 c.cm., 7 cases; over 40 c.cm., 3 cases.

These results are similar in general import to those obtained from examination of the blood, in that they show very wide variation, the majority being within the usual normal limits. They exhibit no recognizable tendency in any one direction, and thus give no support whatever to the view that acidosis is a definite feature in seborrhoeics.

While these figures fail to confirm the opinion that acid excretion in seborrhoeics is increased, they do not disprove the occurrence of hyperacidity—that is, increased degree of acidity as opposed to increased amount of acid—*in the urine of such patients*. This is a point we have not examined, but have reserved for future investigation, since our present concern is simply to obtain evidence as to the occurrence of true acidosis. But if hyperacidity of the urine is present along with normal quantitative excretion of acid, then the quantity of buffer substances excreted must be reduced. This may perhaps be the case, for, as we have already mentioned, Sabouraud found a diminution in phosphate along with hyperacidity. It is obvious, however, that on theoretical grounds, it is unjustifiable to accept hyperacidity of the urine as sufficient evidence of the presence of true acidosis, and our present results show that, *even if hyperacidity does occur*, there is, in fact, no evidence to indicate that acidosis is a constant feature, or even a common feature, in seborrhoeic subjects. As Barber and Semon point out, their subjects—soldiers on active service—were living in very unusual environmental conditions, and, particularly, were on a dietary likely to provoke some degree of acidosis. It seems possible to us that, in their series of cases, an acidosis may have been the precipitating factor in producing seborrhoeic manifestations, especially in view of the dramatic *effects of alkaline therapy recorded by them.*

The majority of the cases investigated by us were of acute and chronic seborrhoeic dermatitis *and seborrhoeic* eczema, with and without secondary impetiginization and septic folliculitis; some cases of severe acne *vulgaris and* rosacea were also included.

CONCLUSIONS

1. We have *found no evidence to suggest the presence* of acidosis in persons subject to *seborrhoeic disorders.*

2. We have *found no evidence to suggest* that there is increased excretion of acid in the urine of seborrhoeic subjects, but we *have not investigated* the question of *their secreting a hyperacid urine.*

3. We have found no evidence to support the alkaline *treatment of seborrhoea*, except where this may be indicated by the nature of the precipitating cause of the attack.

RUPTURE OF THE CORONARY ARTERY

REPORT OF TWO CASES

BY

C. B. BAMFORD, M.D., D.P.M.

SENIOR ASSISTANT MEDICAL OFFICER, RAINHILL MENTAL HOSPITAL

At two recent necropsies at the Rainhill Mental Hospital, the condition of a ruptured coronary artery was found in two patients who had died suddenly, but who were known clinically to have had cardio-vascular degeneration. In each case the cause of death had been certified as cardiac failure and arterio-sclerosis. Though sclerosis of the coronary arteries is by no means uncommon, it is seldom that this condition proceeds to the extent of aneurysmal formation and rupture. In the post-mortem records of this hospital for the last twenty years, comprising nearly three thousand cases, no similar instance of this condition could be found. Its apparent rarity induced me to extend my investigations to a wider source.

In the standard textbooks on medicine and pathology very scanty reference to coronary aneurysms and rupture is made. Kaufman, in his monumental book on pathology, says "haemo-pericardium occurs quite rarely from aneurysms of the coronary artery." Recent references in the literature are practically non-existent, and one must go back thirty years to obtain satisfactory descriptions of this condition. Capps collected nineteen cases of aneurysms of the coronary arteries, and stated that in eleven of these cases death occurred from rupture into the pericardium. He adds, "I was very surprised in reading the literature to learn that, while aneurysms of the heart and of the root of the aorta are comparatively common, so very few instances of coronary aneurysms have been described." The usual site of the dilatation is very near the origin of the coronary artery from the aorta, in the loose cellular tissue described as the periaortic space. This is also a favourite place for interparietal aneurysm of the heart. T. Wardrop Griffith described eighteen cases in which death occurred from rupture into the pericardial sac in exactly one-half. He says: "Aneurysmal dilatations in the course of the coronary arteries of the heart are so uncommon that the experience which fell to my lot of seeing two examples in two successive post-mortems must be unique." With slight differences, history has repeated itself in relation to the two cases about to be described. These differences will be apparent on reading the following account.

CASE I

W. B., aged 64, a patient in this hospital for many years, was a long-standing case of dementia praecox. Though exhibiting many of the characteristics of a chronic dement, he had been employed in rough routine work at the farm for many years. Periodical examination of his physical state revealed the fact that his arteries generally were thickened and tortuous, and his cardiac degeneration was shown by the altered character of his heart sounds. Despite this, he maintained his health and vigour, and was able to work regularly until January 7th, 1931, when he stayed in from his work on the plea that he did not feel well. The next morning he looked ill, and when interrogated replied that he did not feel very well, adding that he had a cold. He was [illegible] to bed in the sick ward, to await the medical [illegible]'s visit. He was found dead a short time after[illegible] just a minute or two after the nurse had taken his temperature. Unfortunately his blood had never been examined for syphilis. At the necropsy the heart *in situ* appeared very large in all dimensions—a typical bullock heart.

As soon as the pericardial sac was opened a dense large coagulum of blood was seen to fill and distend the whole of the pericardium. The recency of the clot was evidenced by the absence of any attempt at organization. The source of the haemorrhage was easily traced to a ruptured aneurysm, about the size of a pea, on the course of the coronary artery on the posterior aspect of the heart in the interventricular groove. The aneurysm was located about an inch from the apex of the heart—the most unusual site. On the anterior surface of the heart there were also two other similar aneurysmal dilatations of a branch of a coronary artery running over the surface of the right ventricle near the cardiac apex. The heart itself (407 grams in weight) was very large, showing hypertrophy of both ventricles, particularly of the left. The aorta (especially the thoracic portion)

Two aneurysms on the coronary artery, as described in Case I. The lower is cut across.

exhibited raised round areas of atheroma irregularly disposed, of the shirt-button variety, which is highly suggestive of a syphilitic aorta. The other arteries were considerably sclerosed. The solid viscera all showed increased density and fibrosis consistent with the usual findings in dementia praecox.

CASE II

S. H., aged 69, a case of dementia, was in very poor bodily health. Her heart was weak and irregular, and a mitral systolic murmur was present. Her arteries, too, were generally hardened. The blood and cerebro-spinal fluid were negative to syphilis. Mentally, she was very dull and confused, and unable to give any account of herself. She died suddenly on December 8th, 1930.

At the post-mortem examination an interesting lesion of the left anterior coronary artery was discovered, which in all probability accounted for the suddenness of her death. The artery was found to have ruptured longitudinally, resulting in a haemorrhagic infiltration of the outer portion of the muscle of the left ventricle. There was no evidence of any aneurysmal formation, although the coronary arteries generally were sclerotic. The heart, weighing 258 grams, showed slight hypertrophy of the left ventricle. Extensive atheroma with ulceration was found in the aorta. The kidneys were small and typically granular. In the brain there were some areas of softening, notably some small perivascular softening in the left basal ganglia and also in the left lobe of the cerebellum.

It will be seen that the special features of interest in Case I were: (1) The presence of multiple aneurysms of the coronary arteries, situated in an unusual position—namely, towards the terminal parts of the artery rather than near the place of origin. (2) The rupture of one of these aneurysms into the pericardium. (3) The condition of the aorta, suggesting a probable syphilitic origin of these aneurysms. In Case II, the rupture of the coronary artery was just the end-result of advanced arterial degeneration, associated with chronic renal disease and cardiac hypertrophy.

I am indebted to Professor Dible for his valuable suggestions and help, and also to Dr. E. F. Reeve for permission to publish the case.

A METHOD OF ANCHORING RADIUM NEEDLES IN THE PHARYNX

BY

J. E. G. McGIBBON, M.B., B.S.

AURIST AND LARYNGOLOGIST, LIVERPOOL EYE AND EAR INFIRMARY

The difficulty of fixation of radium needles when used for interstitial radiation of pharyngeal neoplasms is generally recognized. Not only is accurate insertion of the needles difficult, but also, as the regions are kept incessantly in motion by involuntary swallowing movements, the needles are liable to be expressed from the tissues. Furthermore, displacement is favoured, as the mere presence of a neoplasm in this locality creates a necessity and desire on the part of the patient to rid his throat of increased secretions by hawking and coughing.

The techniques described for fixation of needles include the following: (1) the needles are inserted in pairs from behind forwards and in the opposite direction, and tied in position[1]; (2) after insertion of the needles the threads are collected into a rubber tube, which is brought through the mouth, and the threads are then fastened to the skin of the cheek by strapping[2,3]; (3) firm suturing of the needles *in situ*.[1,3,4] All of the above procedures possess certain disadvantages. Tying the needles together in pairs when in use in the tonsil is an insecure method of fixation; a pair of needles could easily become displaced. The use of a rubber tube in the mouth for at least a week must be very irksome to a patient, and will interfere with deglutition. Traction on such a tube by movements of the tongue could readily dislodge one or more needles. Suture of the needles *in situ* necessitates three wounds per needle: the needle insertion wound, and the wounds of entrance and exit of the suture. In a patient already poorly nourished and suffering from pain and dysphagia such extensive trauma in a septic area presents obvious disadvantages. Moreover, in spite of careful suturing, the needles may become displaced. Birkett states that it is almost a routine procedure at Manchester to give a second anaesthetic and reinsert the needles.

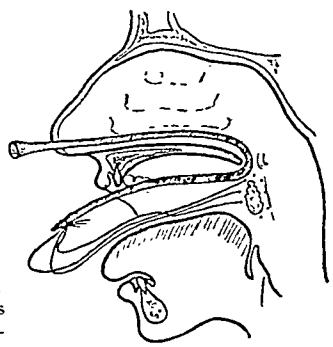

FIG. 1.

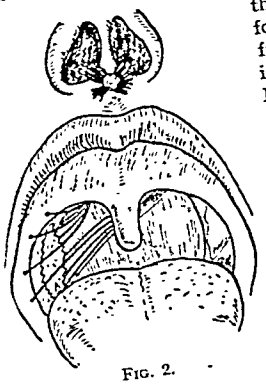

FIG. 2.

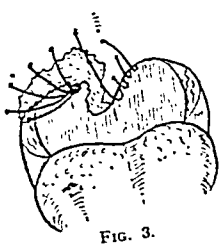

FIG. 3.

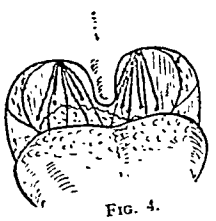

FIG. 4.

DESCRIPTION OF TECHNIQUE

The method described below has been used by me for lesions affecting the tonsil alone (Fig. 2); the soft palate alone (Fig. 3); the tonsil and palate; the tonsil and side of tongue; the tonsil, palate, and side of tongue; and the posterior pharyngeal wall (Fig. 4). It requires good illumination and efficient access. These have been obtained by the use of reflected light from a forehead mirror, and of the Boyle-Davis gag. The needles are inserted in the usual manner through healthy tissue around the lesion, and the threads are left nine to ten inches in length. After insertion of a needle its thread is secured outside the mouth, without any tension, by pressure forceps. When the requisite number of needles have been introduced a soft rubber urethral catheter (about size No. 8), lubricated with liquid paraffin, is passed along the floor of one nasal fossa into the naso-pharynx. As soon as the tip of the catheter is seen below the soft palate it is caught by a pair of Luc's forceps and brought outside the mouth. Half the total number of radium needle threads are then released from the pressure forceps and tied securely to the end of the catheter. Fig. 1 shows the threads tied to the catheter; three threads only have been drawn in the diagram, for purposes of clear illustration. The catheter is now carefully withdrawn from the nose, and immediately the attached threads appear at the nasal orifice they are freed from the catheter. Each thread is gently drawn taut, and, during traction, observation must be kept on the site of insertion of the attached needle in order to prevent accidental withdrawal. These threads are then tied together with a piece of silk or catgut. The lubricated catheter is now passed through the other nasal fossa, and the remaining free threads dealt with in a similar manner. Finally, the two bundles of threads are tied securely together across the columella and the redundant ends cut off (Fig. 2). The patient must be watched constantly until complete recovery from the anaesthetic, in case he should pull on the knot and so displace the entire number of needles.

The presence of the threads in the nose does not interfere with nasal respiration, and appears to cause little discomfort. The threads in the pharynx lie against the posterior and lateral pharyngeal walls, and do not interfere with speech or swallowing. The patients have been able to take ordinary soft food until the fifth day after insertion of the needles, and they have been kept tolerably comfortable during that period by the frequent use of mouth-washes. Owing to reactionary swelling and inflammation of the parts, the patients have been able to swallow only fluids from about the fifth day, until removal of the needles on the eighth or ninth day. Soft food can then be taken again, and ordinary diet gradually resumed in a week to ten days. As a rule, two or three needles have worked out, but as these remain suspended at a visible level in the oropharynx and adhere by moisture to the posterior pharyngeal wall, they can be easily reinserted or removed.

Needles 21.7 mm. in length (active length 10 mm.), 1.65 mm. external diameter, containing 1 mg. radium screened by 0.5 mm. platinum, have been found most convenient for use in the regions discussed above. These needles have been kindly lent by the Liverpool Radium Institute.

A CASE OF ERYTHROEDEMA

BY

FRANK J. LEES, M.B., CH.B.ABERD.

The subject of this report, a female child born in April, 1930, was, until the age of 6 months, an apparently normal healthy baby of contented disposition. Her weight at birth was 8¼ lb. She was not weaned until well on in her illness.

During October the mother noticed that the child gradually went off her feeds, became irritable and fretful, and could not sleep. Marked constipation alternated with occasional passage of loose green stools. Under observation from day to day, the child ran a temperature (99°–100° F.) until about the middle of November, when she became afebrile, and has remained so since. During her illness she never appeared to be in severe pain, nor yet to be actually ill; but she looked miserable and wretched. Extreme restlessness was a marked feature, the child never remaining in the same position for more than a few moments. Photophobia was active during the whole illness, especially marked in the right eye, though neither iritis nor corneal ulcer was present. The eyes were extremely watery and the lids somewhat injected. The lips were cracked, the tongue coated. The pink nose, pink cheeks set in the pale face, watery eyes, photophobia, and aspect of misery, presented a characteristic picture. The child was in poor condition, and appeared to be suffering from a form of pseudo-paralysis, the neck muscles being so weak that she could not hold up her head. There was also great weakness of the leg muscles. Wasting was marked, especially of the shoulders and inner aspect of the thighs, but never to the point of emaciation. Early in December the child's hands and feet were noticed to be of a bluish-red colour, very cold, swollen, and clammy. This colour did not persist, although the coldness remained. At no time were trophic disturbances of hands and feet observed. Kernig's sign was negative; the heart, lungs, and kidneys were normal; but the pulse was frequent, never being below 130, and usually 150. The knee- and ankle-jerks were elicited only with difficulty. There was a copious non-purulent nasal discharge, examination of which showed staphylococci and diphtheria bacilli. Insomnia was very marked. From time to time sweat rashes were observed. Sweating was always excessive. At the beginning of January, 1931, some improvement became evident, the sweating diminished, and there was no recurrence of rashes. The child, however, pacified by nothing the mother could do, remained in a miserable and restless state, and cried incessantly. During her less miserable periods she would scratch her genitals and the lobes of her ears, making the latter bleed. About the middle of January general improvement was noted, the hands and feet became warmer, and the appetite improved. Bouts of crying still occurred, but did not last so long. In the intervals she was quite comfortable, and if shielded from the light opened her eyes, held her head up better, grasped and handled articles, and played with her toes. Gradually the crying and restlessness subsided, and she slept better. The nasal discharge still continued very profuse. Towards the end of that month she opened her left eye well, but the right eye still showed great sensitiveness to light. During February the child gradually gained strength; her muscles increased in tone, and she held her head erect for longer periods of time. She put on weight fairly quickly, the adductor parts of the thighs especially appearing to fill out and become firm. She had then six teeth, and all seemed firmly fixed in their sockets. She still had slight photophobia in the right eye, which soon cleared up. The hands and feet became warm, she lost all signs of misery, and became happy and contented, playing with her toys and taking notice of things going on around her. She now appears to be perfectly well, except for a liability to colds in the head and to bronchial catarrh.

The treatment was purely symptomatic, a mother's patience and care being *facile princeps*. Bromides and chloral were tried, and appeared to give some small relief. Resorcin was thought to diminish the nasal discharge. Early on in the disease the child was partially weaned, and care was taken to provide her with ample vitamins.

COMMENTARY

Erythroedema, or pink disease, has been recognized only recently as a clinical entity. Known in Australia for twenty-five years, it was first accurately described by Swift[1] in 1918, and by Weston in England in 1920. The most constant symptom is a marked change in the disposition of the child. According to Langmead,[2] intolerable itching is prominent; and he relates that Zahorsky mentions two children who continually pulled their hair out. Langmead also says that the deep reflexes tend at first to be exaggerated, but later to become weakened or lost. He remarks that a leucocytosis of from 12,000 to 30,000 is the rule in severe cases. Vipond[3] lays great stress on the pains in the extremities, saying that this suffering produces an abnormal mental condition, characterized by an extremely high degree of irritability and restlessness which has not been observed in any other disease. He also notices a peripheral neuritis in his cases, with diminution or loss of cutaneous sensibility. He says: "I have proved this condition by putting a needle into an inguinal node without the little one suffering intense pain." According to him, the age of onset is from 8 to 18 months, and the duration of illness from four to six months. He found in the lymph nodes in every case a small Gram-positive diplococcus, from which he made an autogenous vaccine which, he claims, gave good results. Parsons[4] thinks there may be some food-deficiency factor present, and suggests yeast.

Erythroedema must not be confused with acrodynia, which is an epidemic disease of adults (Paris, 1928, epidemic). The former is a sporadic disease met with typically in children; it is a self-limiting disease, and recovery is complete in from three to six months.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

THE BINOSCOPE

The binoscope is an apparatus for training binocular vision. The plan of its construction is based upon that which Nature apparently employs for bringing about and maintaining the habitual use of the vision of both eyes simultaneously in this our highest type of sight, briefly as follows:

In an open space we can see the horizon for about half a circle—that is, the combined field of vision with both eyes extends through nearly 180 degrees from side to side. Rather more than one-third of this in the central part, where the vision of each eye overlaps that of the other, is seen with both eyes in binocular vision. In this part each object is seen with both eyes at the same time, yet it is seen as one object, for the two images—one on each retina—fall upon the corresponding points which exist in both retinae where the vision overlaps The lateral parts of the field of vision are seen with

monocular vision. Each lateral part is seen to its limit with the eye on its own side without the help of the other eye. Thus in these lateral parts the objects seen with one eye are not the same as those seen with the other eye; yet both eyes are used at the same time. Hence this is called simultaneous vision to distinguish it from binocular vision. In ordinary vision out of doors, should one eye fail to function we are at once conscious of it, and this is sufficient to bring normal eyes into activity. In our occupations indoors attention is often concentrated on a much narrower field of vision, and one eye may cease to be used without our being aware of it. Thus the sight of one eye only may be used, until a habit of depending upon one-eyed sight is formed.

The plan upon which the binoscope is constructed trains binocular vision by applying the conditions of the natural field of vision out of doors to a more limited field of vision, such as indoor occupations often bring about. This is effected by partially screening the vision of each eye, so that in this narrower field there is a central part for binocular vision and lateral parts for monocular vision, as in ordinary vision out of doors. Each of the lateral parts is seen with one eye only, and this makes us conscious of the failure should one eye cease to be used. Both eyes are thus kept in a state of activity, and the central part of the field of vision, which is not affected by the screening, is seen with binocular vision as in the field of vision out of doors.

This plan has proved remarkably successful in bringing about and training binocular vision, and can be used for seeing both near and distant objects. Thus, the first teaching of the binoscope is apparently a physiological explanation of the manner in which binocular vision is naturally brought about and maintained. The chief medical use of the binoscope is in the treatment of asthenopia, strabismus, and heterophoria. Most young children with squint temporarily lose the squint, and see with binocular vision, when tried with the binoscope. Older children often see double at first. The physiological test for binocular vision is single vision with both eyes, of the same object. This test the binoscope applies. Exercises with the binoscope have proved very successful in giving relief in asthenopia. This appliance was described and illustrated in the *Proceedings* of the Royal Society of Medicine (vol. xxi, Part I, p. 700).

MEDICINE AS A SCIENCE AND AN ART

ORATION TO THE MEDICAL SOCIETY OF LONDON

A general meeting of the Medical Society of London was held on May 11th, with the president, Dr. R. A. YOUNG, in the chair, when Sir JOHN ROSE BRADFORD, Bt., delivered the annual Oration.

Sir John Rose Bradford, who took as his subject "Medicine as a science and an art," said that the last half-century had been marked not only by numerous great discoveries in the realm of natural knowledge, but more especially by the rapid application of those discoveries to the practical needs of humanity. The benefits thereby conferred had led to some confusion as to the real relationship between scientific discovery and the practical application of its results. The demand, ever increasing, for practical applications and benefits was apt to dominate the situation, and might even affect the mental outlook of those whose primary purpose was only to add to knowledge. The chemical or physical problems involved in the production of artificial silk, for example, or in the steam turbine, or in wireless communication were fully appreciated only by the experts in the particular branch of science which was concerned, and frequently they were difficult of apprehension by a worker in another branch, or even in a cognate branch of the same science. When the practice of an art was founded upon the achievements of a science, the differences existing in the modes of thought of workers in the science and those engaged in the art were prone to be accentuated, so that two camps were formed, and it was possible for the one camp to doubt the value or even the very existence of the science in question, while the other camp asserted that all would be well if the so-called art were replaced by something which could be regarded as a science. There were some who doubted whether medicine was a science, but a practitioner could not exercise his art efficiently unless it was scientifically grounded.

The orator introduced a parallel between the profession of medicine and that of the soldier. The soldier, like the doctor, had to realize a situation, and to determine quickly a course of action; he had to have instinct or *flair*, and both soldier and doctor were useless unless their instinct was regulated by sound general principles which owed their origin to the study, in the one case, of the science of war, and in the other, of the science of medicine. He quoted Ruskin's definition, that the work of science is to substitute facts for appearances and demonstrations for impressions. Looked at from one standpoint, medicine was only a branch of biology, most akin to the subdivision of biology known as natural history. Some might be inclined to take a narrow view of medicine, and regard it as merely the physiology of the abnormal, for the connotation of which the terms "pathology" and "pathogeny" had been employed. But the natural history of an animal or plant concerned much more than purely physiological processes, and many phenomena of living organisms could not be fully investigated by the methods of the laboratory alone. If a satisfactory knowledge of the life processes of an animal or plant was to be acquired, the methods of study practised both in the laboratory and in the field were necessary, and it was unfortunate that in biology and in medicine there should be divergence of view as to the relative importance of the one method and the other. It was essential that the pursuit of natural history in the realm of clinical medicine should not suffer because it was supposed to be of less importance or to require a smaller degree of equipment, mental or material, for its pursuit. The two classes of workers must pursue different methods, but both should remember the words of Ruskin.

The darkness of medicine in the ages previous to Harvey was attributable largely to the fact that the book of nature was not consulted, and that reliance was placed on authority. It was Harvey who consulted the book of nature, and proceeded to ask of it a series of masterly questions, finding answers which established the science of medicine. In the progress of science the gift or discovery of a method of inquiry was often of more service even than the discovery of a great fact, and medicine in this respect, through Harvey, had rendered perhaps the greatest assistance to the progress of all biological sciences. The experimental method in recent years had extended the scope of its operations to a remarkable extent. At present much of the work of the biologist and the botanist was performed by its aid. The modern biologist paid an increasing attention to problems capable of solution by the experimental method rather than to the problems of morphology; in other words, function was considered rather than structure. Although medicine was indebted to other sciences, the relationship was not entirely a unilateral one. It was perhaps excusable for

the public to fail to recognize the value of so-called pure research, but those who followed the profession of medicine, and whose daily work afforded them countless instances of the material benefits accruing to their art as a result of such research, should be chary of belittling it even when the practical application was not apparent.

The field of operation for the science of medicine was the study of the phenomena of disease as a whole and the means of its prevention, while the art of medicine was mainly concerned with the problems encountered in the attempt to recognize and treat disease in individuals. No hard-and-fast line could be drawn between the science and the art in given instances, though the knowledge of the prevention of disease might reach a very high level of development from the purely scientific standpoint, while failing in its application owing to imperfections in the art of medicine in the clinical field. He protested that medicine as a science was not a mere appanage of anatomy, of physiology, or even of pathology; there was something more, difficult to describe in words, but which might be summed up as the natural history of man. Clinical medicine, like natural history knowledge in the field, was not easily acquired. It necessitated a long apprenticeship, often long waiting to obtain opportunity, and it was also exceedingly difficult to acquire habits of observation which reached the high standard of scientific accuracy.

In conclusion, Sir John Rose Bradford said that to have a really comprehensive view of medicine attention must not be confined to human medicine. The consideration of disease in animals, at any rate domestic animals, must be included, and this was important, not only from the point of view of the communicability of disease, but from that of checking any tendency to narrowness of outlook or dogma in respect to disease causation. The comparative method had always exercised a broadening influence on the human mind, and might be applied with advantage to medicine, as well as to anatomy and physiology. Further progress must be based rather on the mental attitude of the disciples of medicine than on the mere use of increased instrumental or chemical agencies. It was always possible that great advances might be made by individual discovery, but such discoveries would not only be limited; they would be very difficult of application when removed from the relatively simple conditions of the laboratory to the complex field in which clinical medicine operated. Clinical medicine, as of old, still offered a wide scope for those gifted with real powers of scientific observation, and, important as the experimental method was, and valuable in the instrumental aids it furnished, these were not by any means the sole methods of advance.

TREATMENT OF INTESTINAL AMOEBIASIS

At the meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on May 7th, with Dr. J. G. THOMSON in the chair, Dr. P. H. MANSON-BAHR opened a discussion on modern methods of treatment of intestinal amoebiasis.

Dr. Manson-Bahr said that he had had under observation over a course of years (partly in private practice and partly at the Hospital for Tropical Diseases) some 300 cases of intestinal amoebiasis. In every instance either the vegetative forms of the *Entamoeba histolytica* or its cysts had been found in the faeces, or the typical lesions had been seen by sigmoidoscopic examination and the parasites demonstrated in preparations made from them. Every endeavour had been made to trace the after-history of the cases. Four main methods of treatment had in sequence been adopted. The first few cases, eleven years ago, were treated only by emetine injections. Emetine alone undeniably had a direct action on the parasite, but he came early to the conclusion that although the immediate results were very striking, this drug, given alone, was not sufficient for eradication. A series of 130 cases was then treated by emetine-bismuth-iodide, given in generally recognized therapeutic doses. In 1925, having read in German and Dutch literature of favourable results with yatren, he obtained a supply and employed this drug, given by the oral and the rectal route simultaneously, in some fifteen cases, but for his last 150 cases he had combined yatren with emetine-bismuth-iodide, and this, in his opinion, was by far the most satisfactory line of treatment. He cited some remarkable cases by way of showing that after one radical treatment lasting twelve days permanent cure of often a long-standing condition resulted. What was sold in this country under the name of quinoxyl produced, so far as he could judge, corresponding results. The drug could be taken as a pill, in cachet form, or by enema. Yatren given by the mouth in large doses produced intestinal disturbance; injected per rectum it produced singularly little discomfort. The bowel was first cleansed out, and the solution run in by means of a tube and funnel, the patient being instructed to retain it as long as possible. Some patients developed a raised yellow rash on the following day, but no other sequel had been observed. It had a wonderful effect in healing amoebic lesions in the bowel, but, given by itself, there were relapses, and therefore he combined it with the emetine-bismuth-iodide treatment, injecting the yatren into the bowel in the day, and administering the other preparation at night. Among the cases treated by the combined method, he knew of only two which had relapsed, and these cleared up on repeating the course, and increasing the yatren enema to 5 per cent. strength instead of 2½ per cent., and in no instance had the treatment to be discontinued on account of intolerance. Whenever possible, a sigmoidoscopic examination of the bowel was made before and after treatment. The disappearance of the amoebic lesions had been usually recorded wherever the yatren had come into contact with them, and the remarkable manner in which the ulcers had granulated and epithelialized had been noted. There was evidence also that yatren solution, injected into the rectum, percolated through the lumen of the large intestine. He had no evidence that yatren in pill form was efficacious in eradicating infection, though he believed it helped to prevent relapses.

Dr. G. CARMICHAEL LOW recalled the old treatment of amoebic dysentery with ipecacuanha; there was no question clinically as to the cures produced by that treatment; they were just as wonderful as those with emetine and later treatments. On treating with emetine-bismuth-iodide, it was found that after treatment there were certain periods when parasitical relapse was most likely to occur—one such period, for example, was twenty-one days after treatment. Therefore clinical cures might be fallacious unless the patient was the subject of extended observation. A patient might have no clinical signs for months, and then suddenly relapse, with blood and mucus in the stools. He thought that workers with emetine-bismuth-iodide had been somewhat optimistic in calculating their cures (80 per cent.), and if it had been possible to continue observations for six months, that estimate would have been reduced. Certain cases, also, resisted emetine. With regard to yatren, he did not know that it had yet been proved that it had a specific action on the parasite similar to emetine; on the other hand, equally good results might be obtained with some other form of bowel lavage.

Dr. H. S. STANNUS asked what evidence there was, when healed ulcers were seen in the portion of the bowel

investigated by the sigmoidoscope, that ulcers higher up in the bowel were healed or healing. If such evidence were established, it would mean a very great advance.

Dr. ALDO CASTELLANI, K.C.M.G. (Hon.), said that he had had the opportunity of treating dysentery in many parts of the world, and the conclusions he had reached were similar to those of Dr. Manson-Bahr. The drugs he had used were mostly emetine, stovarsol, and yatren. Emetine gave striking results, but he agreed that in many cases it did not eradicate the infection. Stovarsol was useful in certain cases, but its action on the amoebae was very slight; it was a tonic rather than an amoebacide. Yatren in usefulness he placed next to emetine, but, in many cases, neither emetine nor yatren alone would bring about a complete cure. A combined treatment was necessary, and he favoured emetine and yatren. He had very seldom used the emetine-bismuth-iodide, generally preferring the emetine periodide or similar drugs.

Dr. J. G. WILLMORE said that he had treated about 200 cases of amoebic dysentery by the combined method, and his experience had been identical with that of Dr. Manson-Bahr. It was not too much to say that amoebic dysentery had lost its terror. His own treatment differed from that of Dr. Manson-Bahr only in unimportant detail. He did not quite understand the rationale of emetine-bismuth-iodide. It was introduced with the idea that it was not decomposed too high up in the gastro-intestinal tract, so that the direct irritant effect on the stomach was avoided, and the emetine, which did the work, was liberated more or less where it was wanted. But emetine-bismuth-iodide was, in fact, decomposed in dilute acid solution. One rather interesting point about yatren was that it was opaque to x rays; by radiology they could discover how far the yatren travelled. He confirmed the point about the uselessness of yatren by the mouth. Out of his 200 cases treated by the combined method—an emetine preparation and yatren enema—he could recall only four which had relapsed protozoologically, and as all his patients were pensioners, he had rather good opportunities of following them up.

Dr. W. BROUGHTON-ALCOCK said that intractable infections were sometimes superadded to amoebic dysentery; whether these produced ulceration he was not prepared to say, but he believed that there could be ulceration following amoebic dysentery which was not due to amoebae. He supported the combined treatment.

Dr. PHILIP FIGDOR remarked that not a few cases showed *Lamblia intestinalis* in the stools for quite a long period while amoebae were not found; then after a time there was a relapse, and amoebae reappeared. He had found it desirable, in cases which had apparently cleared up, to continue small doses of ipecacuanha compounds for an indefinite period.

Dr. MANSON-BAHR, in reply, said that in lamblia infections yatren treatment at least cleared up the symptoms. He also expressed a belief that amoebic dysentery led to appendicitis. He spoke of the difficulty of following up cases for a long period in tropical medicine, but said that he had made an effort, in an extensive series of cases, to assess the exact value of each particular line of treatment.

SURGICAL TREATMENT OF GASTRIC ULCER

At a meeting of the Section of Surgery of the Royal Society of Medicine, on May 6th, with Mr. C. H. FAGGE in the chair, a discussion on the surgical treatment of gastric ulcer was opened by Mr. A. J. WALTON.

A few years ago, Mr. Walton said, there had been a revival in favour of the medical treatment of gastric ulcer, and there were still some who claimed that this should be the only treatment; but although alkaline treatment usually effected an improvement it was temporary, and the patient was subject to the usual recurrent attacks of pain. Moreover, with medical treatment there was always a danger of haemorrhage or perforation. A certain amount of discredit had fallen upon surgical treatment, because it had sometimes been undertaken in cases of acute ulcer, and by inexperienced surgeons. Although everyone heard of the failures of surgical treatment, it was not easy to say what proportion these represented of the whole; nor was it possible to obtain accurate statistics of the end-results obtained by medical treatment, though the results of surgical treatment were readily available. The common history in gastric ulcer was that of a middle-aged man complaining of attacks of pain after food, which did not wake him at night, and which were not relieved by taking food. Severe pain was often due to inflammatory changes round the base of the ulcer, and was, as might be expected, generally relieved by medical treatment. If alkalis had no effect, and if the pain was referred to the shoulder, the ulcer was probably deep, and involving the pancreas. Pain of this type was a definite indication for surgical intervention. A second indication was a long history, which meant an ulcer with a fibrous indurated base which would not heal under medical treatment. Diminution in size of the crater, as shown radiographically, must not be taken as evidence of improvement under medical treatment; oedema and swelling of the mucous membrane often gave rise to a misleading picture. A third indication for operation was the failure of medical treatment. Although some physicians held that every case would yield to medical treatment, he was convinced that this would fail in a few instances. Possibly the patient was unable to follow the necessary regime. A dock labourer, for example, could not attend his work and follow out the details of a Hurst diet at the same time. Perforation was an urgent indication for surgical intervention. The question then arose whether any treatment other than simple suture should be undertaken. Ulcers which perforated were nearly always chronic, and therefore more radical treatment was needed than was provided by suture. He had observed among cases treated with simple suture by his assistants at the London Hospital that not one had subsequently been free of pain. Patients with severe haemorrhage required operation as soon as their condition had sufficiently improved. There were a few cases in which a blood transfusion should be performed and operation carried out immediately if life was to be saved. Ulcers with much fibrosis and distortion of the stomach wall should be treated surgically; hour-glass stomach fell into this group, and was usually found in women with generalized ptosis. A final indication was the suspicion of the onset of carcinoma; it had been estimated that 10 per cent. of ulcers became carcinomatous and that 20 per cent. of carcinomata originated from ulcers. He was convinced that many cases continued to receive treatment for ulcers after these had become malignant. The aim of surgery was to bring about a physiological and mechanical improvement, and, that being so, the method employed was really a matter of personal preference. Gastro-enterostomy was once the operation of choice, but nowadays this was not considered sufficient. He had found that among 30 cases of chronic gastric ulcer which had perforated, and in which he had performed simple suture and gastro-enterostomy, there had been no recurrence of symptoms. When the patient was fragile he had found it useful to perform a gastro-enterostomy only; as a result the ulcer usually became small enough to make a more complete operation possible at a later date, and in three or four of his cases perfect healing had apparently occurred. Mr. Walton believed that this explained some of the cases

recorded of carcinoma of the stomach in which recovery had followed gastro-enterostomy; the supposed carcinomata were simple ulcers which had healed. Partial gastrectomy had an advantage in that it removed the ulcer-bearing portion of the stomach, and also part of the acid-secreting mucosa. But partial gastrectomy did not give complete immunity from the later development of gastro-jejunal ulcers. Other advantages of this method lay in the fact that it was easy to develop an expert technique, that results were rapid and convalescence smooth, and that recurrence, apart from gastro-jejunal ulcers, was almost unknown. For small ulcers high up on the lesser curvature, however, he had always felt that the sacrifice of seven-eighths of the stomach was a drastic remedy. There had been evidence, lately, that partial gastrectomy was followed in some cases by pernicious anaemia. With a very large ulcer, local resection was impossible and partial gastrectomy essential. The type of operation was a matter of individual choice, whether it was a Billroth I, a Schoemaker, Polya, Balfour, Moynihan, or the type which he himself preferred. For small ulcers he used simple suture with gastro-enterostomy; larger ulcers called for partial gastrectomy; with very large ulcers a gastro-enterostomy might be all that the patient could tolerate at the first operation, and a gastrectomy might be performed later. With regard to results, the value of a posterior gastro enterostomy lay in its relatively low risk; it did not, however, promise a complete cure. The mortality with partial gastrectomy varied with the surgeon. With most operators the mortality rate was 15 to 20 per cent.

Mr G. GORDON-TAYLOR said that a few years ago medical treatment of gastric ulcers had been in favour, with the result that many cases reached the surgeons as carcinomata. Medical treatment could certainly cure a simple ulcer, and surgical treatment should not be undertaken until diet and alkalis had been tried. It had been estimated that of cases treated medically 40 per cent. remained free from symptoms, 10 per cent. perforated, and 6 to 10 per cent. developed malignant changes in the ulcer. The type of operation used depended on the preference of the surgeon, and the mortality rate depended on his experience and skill. and Moynihan, for example, had a mortality rate of *condit.6* per cent. with partial gastrectomy. Although clinical been for ten years an ardent gastrectomist Mr. still offerylor said that no surgeon, unless he were powers of and of gastric sacrifice, would feel inclined to experimental nl gastrectomy for small ulcers of the mental aids it fuar be had obtained good results from sole methods of ; combined with gastro-jejunostomy.

ulcer [illegible] ulcers he advocated partial penetrati[illegible]ignancy was remo[illegible]oved, danger of [illegible]ulcer wasBLA[illegible]ow with

TREATMENT C

At the meeting of the[illegible]od, and the mo[illegible]y Parasitology of the Royal that 88 per cent. of his cases with Dr. J. G. THOMSON in[illegible]y after the operation, 91 per BAHR opened a discussion on[illegible] cent. in females. There ment of intestinal amoebiasis. [illegible]urbance, and cases were

Dr. Manson-Bahr said that he had even trebling their tion over a course of years, partly [illegible] investigation had and partly at the Hospital for Tropical cent. of his cases 300 cases of intestinal amoebiasis. In [illegible] these was of either the vegetative forms of the *Entamoeb*[illegible]ate in size he or its cysts had been found in the faeces, or this method lesions had been seen by sigmoidoscopic examin[illegible] of anaemia the parasites demonstrated in preparations ma[illegible] stomach them. Every endeavour had been made to t[illegible] Wherever after-history of the cases. Four main method[illegible] women, for ment had in sequence been adopted. The first [illegible]ox ulcers eleven years ago, were treated only by emetine inj[illegible]y, especially [illegible] a partial [illegible]ecent the operation of choice was a gastro-gastrostomy with resection of the ulcer. Partial gastrectomy gave good results in men. In cases of severe haemorrhage he thought it advisable to postpone operation until the bleeding stopped. With perforation he preferred to suture the ulcer and drain the wound.

Mr. C. A. JOLL said that with ulcers on the lesser curvature, including those giving rise to hour-glass contraction, he performed a retrocolic gastro-enterostomy; with large and penetrating ulcers involving the posterior wall and greater or lesser curvature he gave a blood transfusion and saline, and then did a partial gastrectomy. He had found the results of jejunostomy to be disappointing, and embarrassing to the surgeon at a later operation. In the rare cases of ulcers on the anterior or posterior surfaces only, not involving the curvatures, local excision with gastro-jejunostomy seemed to him to be the operation of choice.

Mr. J. MORLEY agreed that no one measure was suitable for all ulcers. He did not, however, believe that 10 per cent. of ulcers acquired malignancy, and thought that there was still a tendency to overestimate that danger. He believed that the 20 per cent. of carcinomata said to arise in a simple ulcer were probably growths simulating ulcer. The operation which he preferred was that of Schoemaker, in which he had been able to reduce the mortality to 2.5 per cent. in a series of 119 cases. These deaths had been due to pulmonary complications and not to leakage at the so-called dangerous angle. The clinical results were good, and there was less likelihood of anaemia than after a Polya operation, in which a large part of the gastric mucosa was removed. He thought more courage was desirable in the treatment of bleeding ulcers; delay in operation sometimes resulted in death from haemorrhage.

Mr. CECIL ROWNTREE said that for a penetrating ulcer distorting the stomach partial gastrectomy was undoubtedly the correct treatment. With regard to the small ulcer on the lesser curvature, he asked how many of his hearers would contemplate a partial gastrectomy in their own case. He had tried jejunostomy for these cases, and had obtained excellent results with some patients, but poor results with others. He was convinced that haematemesis should be treated by exploration and suture.

Professor C. A. PANNETT agreed that surgical principles should be applied to the treatment of a bleeding ulcer. He also believed in the value of gastro-jejunostomy in cases with very large ulcers, and he had found pyloroplasty to be useful in cases of this kind. He put in a plea for the use of the Billroth I operation whenever possible; it had the advantage of restoring the stomach to an approximately normal state, and gave results slightly better than those of the Polya operation.

Mr. J. CUNNING thought it was possible that perforation of an acute ulcer sometimes occurred. He agreed with Mr. Morley that the number of ulcers becoming malignant had been overestimated. With high ulcers difficult of access he found that more room could be obtained by dividing the last two costal cartilages and carrying the wound transversely as well as vertically.

In replying, Mr. GORDON-TAYLOR said that his experience of operative intervention in haemorrhage was not small; he was convinced that interference was unwise. He had found that food introduced by means of a jejunostomy provoked a copious flow of acid juice in the stomach, and tended to retard healing of the ulcer. Mr. WALTON said that though secondary anaemia was common after partial gastrectomy he had not yet encountered a case of secondary anaemia becoming pernicious, and he supposed that it was extremely rare. Like Mr. GORDON-TAYLOR he preferred to drain cases of perforated gastric

ulcer. He thought it unlikely that acute ulcers perforated. In forty post-mortems of perforation cases the base of a chronic ulcer was found to be the site in every case, although one was associated with multiple acute ulcers.

EPIDEMIC ENCEPHALITIS

At a joint meeting of the Manchester Medical Society and the Pathological Society of Manchester, held under the chairmanship of Mr. J. HOWSON RAY, Professor ARTHUR J. HALL delivered an address on "Epidemic encephalitis: yesterday, to-day, and to-morrow."

The lecture was divided into three parts. Under the heading "Yesterday," an account was given of the acute cases, which, first appearing in 1916, had recurred in epidemic waves of varying extent during the following seven or eight years. Attention was called to the periodicity of their recurrence, to the variability of onset in individual cases—sometimes gradual, at other times remarkably sudden—and to the extreme differences of reaction to infection. In some cases the acute attack presented no diagnostic features, in others there were quite definite signs, while in a third group there was no recognizable illness at all, the first symptoms appearing only at a later period and in more chronic form. The more immediate sequelae, such as respiratory anomalies, sleep disorders, moral changes, muscular spasms, and various endocrine disturbances, were discussed. The frequency with which these complications seemed to replace one another in the same patient was emphasized, and the remarkable attacks known as oculogyric spasms were referred to in some detail. During the last five or six years the number of acute cases had steadily diminished. Undoubtedly sporadic cases were still occurring, but they were few in number, and in this country no epidemic outbreak of any magnitude had followed that of 1924. To-day it was the chronic progressive disease which showed itself, chiefly, though not solely, as Parkinsonism.

The lecturer drew attention to the many variations as regards extent, rate of progress, and complications of Parkinsonism. The varied means by which youth overcame the motor disabilities to which the disease gave rise were illustrated by photographs of cases showing different postures and types of gait. He referred to his apparatus for measuring the rate of arm movements and its value in grading individual cases, in estimating their progress, and particularly in unmasking slight cases in which no slowness had been noticed by others or was admitted by the patient. In regard to the pathological side, mention was made of the destruction of cells in the substantia nigra found in cases of Parkinsonism. The morbid histology of these cases fully endorsed the view, held by most clinicians, that Parkinsonism was a chronic progressive encephalitis of an active kind rather than a mere passive residual effect of the acute attack.

Under the heading of "To-morrow" Professor Hall discussed two important questions: What was the future of those mild and partial cases of Parkinsonism which had so far remained stationary for periods varying from seven to even ten or eleven years? Had the activity of the process ceased or was it only temporarily arrested? As most of the patients were young persons, at an age when marriage and choice of occupation had to be considered, important decisions often depended on the proper answer to this question. The difficulty was great because of the absence of precedent. Professor Hall discussed the possibility of further epidemic waves. While there was evidence that since 1924 the number of new cases had been steadily diminishing, yet, judging by the behaviour of other neurotropic epidemics, it would be rash to prophesy that they would continue to do so.

MARIE'S ATAXIA

At a meeting of the Devon and Exeter Medico-Chirurgical Society, held on April 23rd, with Dr. J. R. HARPER, the president, in the chair, Dr. C. J. FULLER showed a girl, aged 12, suffering from symptoms which, he considered, warranted a diagnosis of Marie's ataxia. According to the mother, attention was first drawn to the condition some eight months ago, by the occurrence of four convulsive attacks. No further fits had taken place, but the girl had been noticed to be "getting weak on her legs" for the last few months. Examination revealed primary optic atrophy in both eyes and nystagmus in all directions. The knee- and ankle-jerks were increased, and the abdominal reflexes were present. Both plantar responses were extensor. Tremor of the hands was obvious, and Rombergism positive, the girl tending to fall to the right. There were no gross sensory disturbances. Dr. Fuller said that the diagnosis lay between disseminated sclerosis, juvenile tabes, Friedreich's ataxia, and Marie's ataxia. Disseminated sclerosis was rare in a child of that age, and progress was too rapid. In juvenile tabes reflexes were absent, and in Friedreich's ataxia the lower tendon reflexes were also absent and disc changes rare. No treatment of any value was known, and the course was one of steady deterioration.

GLANDULAR LIPOMA

Dr. ROBB showed, for Mr. Candler, a glandular lipoma, or "hibernating gland," removed under local anaesthesia from the infrascapular muscle of a man, aged about 45. In situation the tumour was some 3 inches from the vertebral border of the scapula. Microscopical section showed it to be a glandular lipoma, a tumour of rare occurrence in man, although it was found in certain animals as a normal structure, and there playing a central part in hibernation. Functionally, it was in relationship with the thyroid and adrenals in hibernating animals. Attention had been drawn to this interesting and rare type of tumour in the *British Journal of Experimental Pathology* in August, 1920.

At a meeting of the Society of Public Analysts, held at the Chemical Society's Rooms, Burlington House, on May 6th, Mr. E. J. GUILD demonstrated a new development in filter papers. The paper contains at least 99 per cent. of alpha-cellulose, with about 0.01 per cent. of ash. It is extraordinarily strong when wet, and offers great resistance to alkaline solution, such as caustic soda, etc. It is suitable for the rapid filtration on a large scale of coarse or gelatinous substances, and is useful for all but the most delicate analytical work. Mr. N. L. ALLPORT demonstrated a new method for detecting decomposition products in anaesthetic chloroform. The decomposition of medicinal chloroform, resulting in phosgene formation, leads to the presence of free hydrochloric acid due to action on the alcohol which is added as a preservative. The silver nitrate test will not detect less than ten parts of free acid per million. This new test, capable of detecting one part of free hydrochloric acid in a million parts of chloroform, is based upon the condensation of resorcinol and vanillin by the free hydrochloric acid, with the formation of a red acidic dye. By subsequent treatment with alkali a pink aqueous layer is obtained, the intensity of the coloration varying with the quantity of impurity present. Mr. J. N. RAKSHIT read a paper on contaminations in morphine deposited in the *British Pharmacopoeia* process for the analysis of opium. The morphine obtained in the determination of the alkaloid by the *B.P.* process contains from 5 to 6 per cent. of other alkaloids, consisting principally of codeine. A modified method was described in which a lime solution of the opium, prepared according to the *B.P.* process, is extracted with benzene prior to precipitation with ammonium chloride. This yields a much purer morphine than the original process.

Reviews

DISEASE IN CHILDHOOD

Dr. ROBERT HUTCHISON'S well-known *Lectures on Diseases of Children*[1] has now reached its sixth edition, and it is almost enough to say that this has all the good qualities of its predecessors. There is evidence of careful general revision, and three new chapters on diet after infancy, asthma, and splenomegaly have been added. The book now contains thirty-nine clinical lectures on all the common and important diseases of infancy and childhood. These lectures are addressed to medical students, and the series is determined as to its length and character by the limitations of time allotted to the subject in the medical curriculum. It is therefore a clinical and practical introduction of the student to a subject which gives him little anxiety from the examination point of view, but which will at once form an important part of his responsibilities in medical practice. There are many good textbooks on paediatrics, but we do not know any one which achieves so well this purpose of a general and practical introduction of the student.

Above everything else the lectures are interesting, and the difficulty of teachers in dealing with this subject is to engage the interest of the student, whose immediate anxieties are not medical practice, but examinations. Dr. Hutchison succeeds in doing so by presenting essential clinical features, leaving behind him much of the usual baggage of pathology and biochemistry, and, like Julius Caesar, travelling light—*impedimentis relictis*. But the success of these lectures, both as spoken and written, is due to other special qualities in the author. He knows exactly what he wants to say, and can say it in terse and clear language. He has a critical and sceptical mind, and a dry satirical humour in dealing with "ingenious theories." He has an unusual gift of drawing a clinical picture in a few telling phrases. And he knows how to refresh the dry places with an apt quotation: for example, he leads his students into the arid desert of infant feeding with a verse from Omar Khayyám, and throughout the book he frequently picks a flower from great literature to adorn and illustrate his argument—from Wordsworth, Charles Lamb, Kipling, Stevenson, and the English Prayer Book. Indeed, in his own writing, he is a master of English style, and in his pages the reader will find nothing of uncouth scientific jargon or of medical slang.

One or two minor criticisms may be made. The chapter on tuberculosis is hardly up to the general standard in interest and merit; it contains too much pathology and too little clinical material. We suggest that it might be improved in a future edition. A still smaller blemish is that the date of appearance of the English edition of Glisson's *De Rachitide* is given in this and in the previous edition as 1681; the date should be 1651. The book is a model of clinical teaching and medical writing. It is read widely, no doubt, by those who listened to the lectures, and can be recommended as a textbook not only to medical students, but also to practitioners who look back with regret to their brief and casual attention to the subject as undergraduates.

A SURVEY OF TUBERCULOSIS

The volume on the Results of Tuberculosis Research,[2] edited by Professors ASSMANN, BEITZKE, BRAEUNING, and ST. ENGEL, is the second in a series which comprises papers dealing with various aspects of the tuberculosis problem; the previous part was reviewed in our columns on October 11th, 1930 (p. 603). The first paper, by Dr. W. Blumenberg, is a good critical review of the literature on the so-called "filterable stage" of the tubercle bacillus. The old observations of Spengler and of Much are recalled, together with the newer observations of Sweany and of Kahn, in their relation to the possible existence of a developmental life-cycle. After carefully summarizing the experimental evidence, and discussing critically the technique employed, the author comes to the conclusion that convincing evidence in favour of the existence of an ultramicroscopic form of the tubercle bacillus has not so far been produced. Even the role of the granules in the development of the bacilli is undetermined. The position at the moment is, in fact, very much as it has been for the last twenty years.

In the second paper, Dr. Hermann Loeschke and Dr. Elisabeth Dehoff deal with the pathological anatomy of apical tuberculosis. Why the apex of the lung is peculiarly susceptible to tuberculous disease is a question that has puzzled a great many thinkers, and is one to which no satisfactory answer has ever yet been given. The authors of this paper favour Orsós's hypothesis. In opposition to Freund and to Hart, who taught that the apex was constricted by the first rib and was therefore unable to expand freely, Orsós believes that it is the best-ventilated part of the whole lung. By the use of various models he has convinced himself that, on account of the conical shape of the lung, the downward pull of the diaphragm is concentrated chiefly at the apex. Dr. Loeschke himself has adduced evidence to suggest that the effect of the diaphragmatic pull varies according to the degree of divergence of the thorax, being felt most at the apex in long narrow chests. He states that nearly everyone at puberty passes through a stage in which the growth in length of the chest is greater than the growth in breadth; the result is that in the young adolescent the chest tends to be of the long and narrow type, so frequently associated with pulmonary tuberculosis (*habitus phthisicus*). Taking this in conjunction with the fact that apical lesions are uncommon before puberty, while they are present in most town-dwellers by the age of 25 years, the author concludes that the phthisis of young adult life is determined by mechanical changes in the form of the thorax.

Space does not permit a summary of the remaining articles. Those by the late Dr. Robert Meyer-Bisch on the mineral metabolism and its relation to diet, by Dr. Gustav Liebermeister on bilateral artificial pneumothorax, and by Dr. Lutz Schall on the interlobar fissures are of considerable interest, containing as they do a record of a number of facts and original observations. Others, such as those on types of institutional treatment, and the selection of patients for sanatoriums, are mere discussions of an already well-worn topic.

There is much to be said for a book such as this, which is essentially a collection of monographs, and we do not think that anyone interested in tuberculosis will fail to be attracted by it.

PRACTICAL ANAESTHETICS

The Practical Handbook Series of intermediate textbooks has now been enriched by the inclusion of a new edition of Dr. C. F. HADFIELD'S *Practical Anaesthetics*,[3] which is described by the author as produced "for the student and the general practitioner," so that it is really elementary rather than intermediate in its scope. That the teaching is the outcome of wide experience and ripe judgement is implicit throughout the volume, and in general terms it can be affirmed that the extremely difficult problems

[1] *Lectures on Diseases of Children.* By Robert Hutchison, M.D., F.R.C.P. Sixth edition. London: E. Arnold. 1931. (Pp. viii + 487; 104 figures. 21s. net.)

[2] *Ergebnisse der gesamten Tuberkuloseforschung.* Herausgegeben von H. Assmann, H. Beitzke, H. Braeuning, St. Engel. Band ii. Leipzig: G. Thieme. 1931. (Pp. 490; 106 figures. M.43.)

[3] *Practical Anaesthetics.* By Charles F. Hadfield, M.B.E., M.D. Second edition. London: Baillière, Tindall and Cox. 1931. (Pp. xiv + 336; 41 figures. 7s. 6d. net.)

of what should be omitted have been solved in a satisfactory way, though there will be individual anaesthetists who would have chosen topics for omission rather differently. Further, as befits a practical series, the practical note is firmly struck and held throughout.

Dr. Hadfield clearly knows his own mind, and those of his colleagues whose experience is the longest and the widest will be the first to applaud the general combination of common sense and scientific accuracy in his teachings. Good as the book is, however, it could have been made distinctly better by more careful attention to arrangement of the material and by increased lucidity and compression in composition. To give an instance of what is meant, the first chapter (after the historical introduction) begins the study of anaesthesia by considering, in order, vomiting, delayed chloroform poisoning, massive collapse of the lung, preparation, examination, after-treatment—and this in a textbook to be put in the hands of medical students! The next chapter takes up the signs and symptoms of anaesthesia and the use of alkaloids as premedication, two topics which, though in one trifling respect they may impinge on one another, should certainly be dealt with as entirely separate. Before leaving the question of the signs of anaesthesia a mild protest must be lodged against the prominence given all through the book to the condition of the corneal reflex, which precedes all mention of muscular relaxation as a sign of anaesthesia. One of the common faults of the inexperienced administrator is that he is apt to be constantly fiddling with the cornea instead of concentrating on the respiration and the muscular system; and this book will, it is to be feared, encourage rather than discourage the tendency. A really expert anaesthetist does not trouble about what pupillary or corneal reflexes his patient exhibits, and the drawback of bringing up students to test them is that they so easily get into the habit of relying on these fallacious signs as their main indications of the patient's condition.

The illustrations are adequate, if undistinguished; but the author frequently mentions them in his text by number without indicating on which page they can be found—a habit that will irritate some of his readers. The lumbar puncture needle illustrated on page 239 must be a good deal less than actual size; some indication of scale might well be given. The statement that no deaths have occurred attributable to percaine is, unfortunately, a long time out of date.

DISEASES OF THE INTESTINE

The well-illustrated volume *Maladies de l'Intestin*[4] is the first of a series of three which will reflect the teaching of Dr. R. BENSAUDE, who for twenty years has specially organized his clinic at the hospital of Saint-Antoine in Paris on this branch of medicine. It is a piece of team work in which he and his hospital colleagues and assistants have taken part. In his introduction Dr. Bensaude expresses deep regret that the premature death of his colleague Professor Paul Lecène has deprived the reader of a review of the surgical aspects of diseases of the sigmoid and rectum. Memorial volumes of Professor Lecène's surgical pathological teaching are being brought out by his pupils, and the first, dealing with diseases of the mamma, has recently appeared. Dr. Bensaude, who takes a special interest in diseases of the lower bowel, begins with a copiously illustrated account of anoscopy, rectoscopy, and sigmoidoscopy, and then discusses the indications and contraindications, technique, and interpretation of biopsies of ano-rectal growths and inflammatory formations. There are two articles dealing with radiological problems of the large intestine and constipations and faecal tumours (stercoromas and stercoliths) of the rectum and sigmoid. The most important article, contributed by Drs. Bensaude, Rivet, and Godard, and occupying a third of the volume, deals comprehensively with gastro-intestinal syphilis; the various forms of gastric syphilis are described in great detail and well illustrated by naked-eye, microscopical, and radiological figures; syphilis indeed maintains its reputation here as the great imitator of other diseases. The lesions of the intestine and rectum follow, and each section is provided with a bibliography, that on gastric syphilis extending to five pages, so that it is a veritable monograph. In another article chronic diarrhoea in adults is critically considered, and Dr. Bensaude concludes the volume with an account of the treatment at French spas of diseases of the alimentary system.

[4] *Maladies de l'Intestin.* Série I. Par R. Bensaude, avec la collaboration de L. Rivet et A. Cain. Paris: Masson et Cie. 1931. (Pp. 544; 97 figures. 55 fr.)

"SIXTY CENTURIES OF HEALTH AND PHYSICK"

It is the fashion these days, in the writing of popular histories, to begin with the amoeba, with the dawn of Creation, or with the condensation of vapour on the cooling surface of the earth. One cannot, it seems, start too soon. A book about the origin of man will begin with the origin of the world, about the origin of the world with the origin of the universe, and a book about disease with the origin of life. In *Sixty Centuries of Health and Physick*[5] Mr. S. G. BLAXLAND STUBBS and Mr. E. W. BLIGH, with more right on their side than many authors, have felt compelled to follow the fashion. For, as they point out, bacteria have been found in the coprolites of fish of the Carboniferous period, while dinosaurs suffered from dental decay, rheumatic affections, and osteomyelitis. Disease not only preceded man but appeared in the earliest men known to us, for Pithecanthropus had an exostosis on his femur, and Pott's disease has been found in the spine of a Neolithic man. These remarkable facts have driven the authors further back than their contemplated sixty centuries, and the title of their book is a modest understatement of the difficulties of the work they have so ingeniously undertaken.

In the preface they emphasize the fact that this is not a history of medicine, but an attempt "to follow in outline the evolution of ideas in the long quest for health." As Sir Humphry Rolleston says in his introduction, they have "successfully brought out the importance of the preventive idea which should permeate the teaching, practice, and research of the medicine of the future." And in the past the most successful ideas have been those concerned with public health and sanitation. The best civilizations seem to have had the best water supply and the best drains. About 3500 B.C. private houses in Mohenjo Daro, a town in the Indus Valley, had lavatories and bathrooms with "waterproofed brick floors," and brick-built drains in the streets took away household sewage. Archaeological research has shown that the Egyptians had bathrooms and efficient drains in their houses, and at Knossos in Crete it has revealed a most elaborate system of sanitation with water closets similar to the modern type. Hygiene was centuries in advance of medicine and therapeutics. Disease was caused by devils, and could be treated only by powerful magic and incantations, or by such remedies as this Byzantine prescription for epilepsy: "Take a nail of a wrecked ship, make it into a bracelet and set therein the bone of a stag's heart taken from its body while alive; put it on the left arm: you will be astonished at the result." It was 3,000 years before clinical medicine

COD-LIVER OILS AND IRRADIATED PREPARATIONS

The Norwegian State Vitamin Research Institute has published an interesting pamphlet by Professor Poulsson, who has collected the evidence regarding the relative actions on rickets of cod-liver oil and of irradiated ergosterol. Two clinical investigations have been carried out in America on this subject. In both cases the activities of a cod-liver oil and of a preparation of irradiated ergosterol were measured in rat units and the action of equivalent quantities on children was determined. Barnes, Brady, and James[1] found that cod-liver oil given in doses of three teaspoonfuls daily (1,400 rat units of vitamin D) prevented or cured rickets in 95 per cent. of a group of 64 children and produced marked benefit in 98 per cent., whereas irradiated ergosterol in a daily dosage of 1,250 rat units of vitamin D prevented or cured rickets in only 44 per cent. of a group of 57 children. De Sanctis and Craig[2] found that a daily dose of cod-liver oil equivalent to 1,400–1,700 rat units completely protected 97 per cent. of a group of 100 children, whereas viosterol in daily doses corresponding to at least 3,000 rat units protected only 77 per cent. of a group of 123 children. Similar results were obtained by Massengale and Nussmeyer, who compared the actions of cod-liver oil and irradiated ergosterol in preventing leg weakness in chickens. They concluded that activated ergosterol was much less effective than the rat-equivalent amount of cod-liver oil in the prophylaxis of this condition.

Poulsson discusses these results, and attributes the superiority of cod-liver oil in the treatment of human rickets to the fact that it contains vitamin A as well as vitamin D. In experimental work on rats the diet is carefully arranged to contain an adequate amount of vitamin A, and as the bone changes studied are due solely to deficiency of vitamin D, they are readily cured by vitamin D alone. The diet of children of the poorer classes is deficient, however, in all animal fats, and for this reason the condition is more complicated. Cod-liver oil, therefore, which contains both the fat-soluble vitamins, produces better results in children than does irradiated ergosterol, which contains only vitamin D.

A complicating element in the nutritional evaluation of cod-liver oils is the variability of the vitamin content figure. Further complexity is introduced by the fact that the methods of assay of cod-liver oil are in a state of confusion. As regards vitamin D, the method of assay of the Pharmaceutical Society is generally accepted in this country. According to this, one rat unit means an antirachitic action equivalent to 0.0001 mg. of the standard irradiated ergosterol supplied by the Medical Research Council. In Norway, however, Poulsson has adopted a procedure in which the rat unit is less than half the British rat unit. Norwegian methods will therefore give a rat-unit value for cod-liver oil two to four times greater than that given by the British methods. The American Council of Pharmacy and Chemistry has proposed yet another method for measuring vitamin D, in which the unit is about six times the British unit. The value of the rat unit of vitamin D varies, therefore, over a twentyfold range, and the term means very little unless the method adopted is stated.

A report entitled "The relative values of cod-liver oils from various sources" has been prepared by Professors Drummond and Hilditch for the Empire Marketing Board.[3] The chief aim of this investigation was to determine the vitamin content of the cod-liver oils produced in Newfoundland and Scotland, but various other problems are discussed. As regards the estimation of vitamin A, the authors consider that the method adopted by the *United States Pharmacopoeia* is unsatisfactory, and may give indefinitely large errors with oils of exceptionally high and low potency. They show that there is a close correlation between the colorimetric method (blue colour with antimony trichloride) and satisfactory biological tests. Generally the A and D values of oils run parallel, and hence for ordinary purposes the medicinal property of a liver oil is indicated by the relatively simple colorimetric test. Oils from Newfoundland and Iceland have a natural yellow colour which is deeper than those from Norway, but there is, unfortunately, a belief that the colour indicates unsatisfactory technique in extraction. Professors Drummond and Hilditch find, however, that "it is certain that the yellow colour of this product is natural and is associated with a high vitamin activity. The same is true of many Icelandic oils, and of some produced in Scotland. The pale oils derived from the Lofoten fishing are, generally speaking, of low vitamin activity." They have analysed a large number of oils from different sources, and their figures show that, when measured by a uniform standard, the Newfoundland and Icelandic cod-liver oils have a vitamin A content about twice that of the Norwegian oils. The values for Scottish oils occupy an intermediate position.

The report includes details of the methods of manufacture of cod-liver oil in Scotland and in Newfoundland, and it should do much to dissipate a certain prejudice that has arisen from misleading statements about the Newfoundland oil. Incidentally, the authors mention the rather startling statements made by Aghuhr regarding the toxic actions which he claimed were produced on the heart by cod-liver oil. This

could worthily take its place beside hygiene, promoted there by Hippocrates, who said: "It is necessary, therefore, to learn the nature of such diseases." During the Middle Ages medicine and hygiene were replaced by superstition and unwholesome smells, until, with the fall of Constantinople, Greek culture and science once more showed men how to think and how to live. A third of the book is devoted to these movements, and the rest to the growth of modern medicine. In the sixteenth century Fracastoro showed that disease could be spread by contagion and by infected articles, and introduced the word "fomes." In the seventeenth century Kircher, a Jesuit, saw further into the nature of infection when he said, "Little worms that cause the plague are very small and imperceptible." Then Pasteur and Koch, in the nineteenth century, discovered the bacteria that had preceded man in the struggle for existence as far back as the Carboniferous period. It is a fascinating story.

At a feast of good things it is perhaps ungracious to grumble at the service; nor should one ask for more. But to describe Malpighi as "that profound and immortal investigator with the microscope," and to call Pepys "the avidly inquisitive Mr. Pepys," shows a lack of verbal discrimination irritating in a book meant for adult readers. In the final chapter, on the epoch of modern medicine, no notice has been taken of modern psychological theory and practice. A still more curious omission is the discovery of blood transfusion, and the reference to it in Pepys's diary, where he writes: ". . . but as Dr. Croone says, may, if it takes, be of mighty use to man's health for the amending of bad blood by borrowing from a better body." On page 6 there is an incomplete sentence in line 3. The illustrations are excellent and well reproduced. This is certainly a book to borrow, if not to buy.

NOTES ON BOOKS

We welcome the appearance of a new and cheaper edition of the surgical classic familiarly known to generations of medical men as Hilton's *Rest and Pain*.[6] This is a reprint of the fifth edition, edited by the late Mr. W. H. A. Jacobson, surgeon to Guy's Hospital.

The fiftieth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*[7] embodies the text of the various communications brought before the society during the session ended April, 1930, together with the reports of the transactions during 1929–30 of the North of England, Midland, and Irish Ophthalmological Societies, and of the proceedings of the Oxford Ophthalmological Congress, 1930. The volume also comprises a comprehensive general index to the *Transactions* of the society (volumes xli–l) for the years 1921–30.

In the preface to the forty-seventh annual volume of *The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland*[8] for the session 1929–30 the publishers announce that they propose to omit from future issues all alphabetical lists of papers, retaining other customary information. This decision has been made in response to a number of suggestions that the volume might receive more liberal support in an abridged and less expensive form. We take this opportunity, therefore, of again emphasizing the usefulness of the *Year-Book* as an authoritative and convenient guide to the work of numerous societies and Government institutions in many branches of science, literature, and art. The medical section of the present volume, which is similar in scope and arrangement to its predecessor, includes lists of reports and other medical publications issued by the Ministry of Health, the Medical Research Council, the British Medical Association, and the Royal Society of Medicine.

Röntgen Technique,[9] by Dr. KURT KIRSCHMANN, is a well-planned manual which should be of value to students of radiology and *x*-ray assistants who are conversant with the German tongue. The sections on general electrical and *x*-ray physics and apparatus are admirable, and profusely illustrated; they occupy about three-quarters of the book. The remaining quarter of the volume is devoted to radiographic and radiotherapeutic technique. These sections might with advantage be enlarged at the expense of the physical sections. The reproductions of normal radiograms are in the main of good quality, and it is a pity that they are not more numerous. Apart from these points the book is to be recommended.

The fourth volume of *Fortschritte der Sexualwissenschaft und Psychanalyse*,[10] edited by Dr. WILHELM STEKEL, contains articles by the editor on the difference between Freud and himself, the psychology of compulsion neurosis, and psycho-analysis (he prefers the term psychanalysis), and education, and short papers by other contributors on psycho-analysis in general practice and dream interpretation.

Rest and Pain. A Course of Lectures on the Influence of Mechanical and Physiological Rest in the Treatment of Accidents and Surgical Diseases, and the Diagnostic Value of Pain. By the late John Hilton, F.R.S., F.R.C.S. New edition. London: G. Bell and Sons, Ltd. 1930. (Pp. xx + 514; 105 figures. 5s. net.)

Transactions of the Ophthalmological Society of the United Kingdom. Vol. l. London: J. and A. Churchill. 1931. (Pp. xxxvi + 946; illustrated. 30s.)

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland. Compiled from official sources. Forty-seventh annual issue. London: C. Griffin and Co., Ltd. 1931. (Pp. vii + 384. 18s. net.)

PREPARATIONS AND APPLIANCES

MODIFIED LÖWENBERG FORCEPS

Dr. GEORGE C. CATHCART (consulting surgeon, Throat Hospital, Golden Square) writes: At a meeting of the Laryngological Section of the Royal Society of Medicine, held at Nottingham last year, several of the speakers in the discussion on adenoids advanced the opinion that catarrhal deafness was not caused so much by a central mass of adenoids as by the small masses in Rosenmüller's fossae. This is a revival of the teaching of the late Dr. Edward Woakes, who was the pioneer of nasal surgery in this country. He pointed out that it was easy to remove the central mass of adenoids with the curette, which was the instrument generally used, but it was not a good instrument with which to remove the smaller masses in Rosenmüller's fossae, and it was these masses that caused

the inflammation which spread up the Eustachian tubes, thus leading to catarrhal deafness. He therefore devised his modification of Löwenberg's original forceps. These forceps enable one to remove the masses in the fossae under the guidance of the finger of the left hand. I have further modified his forceps by making them sharp cutting forceps with a male and female blade. There are two sizes, so that the larger can be used for the central mass and the smaller can get into the fossae of Rosenmüller of children quite easily. The forceps are made by Mayer and Phelps, who made the original forceps for Dr. Woakes

British Drug Houses Ltd. inform us that the vitamin A concentrate noticed in the *Journal* of May 2nd (p. 757) is now issued under the name "avoleum."

COD-LIVER OILS AND IRRADIATED PREPARATIONS

The Norwegian State Vitamin Research Institute has published an interesting pamphlet by Professor Poulsson, who has collected the evidence regarding the relative actions on rickets of cod-liver oil and of irradiated ergosterol. Two clinical investigations have been carried out in America on this subject. In both cases the activities of a cod-liver oil and of a preparation of irradiated ergosterol were measured in rat units and the action of equivalent quantities on children was determined. Barnes, Brady, and James[1] found that cod-liver oil given in doses of three teaspoonfuls daily (1,400 rat units of vitamin D) prevented or cured rickets in 95 per cent. of a group of 64 children and produced marked benefit in 98 per cent., whereas irradiated ergosterol in a daily dosage of 1,250 rat units of vitamin D prevented or cured rickets in only 44 per cent. of a group of 57 children. De Sanctis and Craig[2] found that a daily dose of cod-liver oil equivalent to 1,400–1,700 rat units completely protected 97 per cent. of a group of 100 children, whereas viosterol in daily doses corresponding to at least 3,000 rat units protected only 77 per cent. of a group of 123 children. Similar results were obtained by Massengale and Nussmeyer, who compared the actions of cod-liver oil and irradiated ergosterol in preventing leg weakness in chickens. They concluded that activated ergosterol was much less effective than the rat-equivalent amount of cod-liver oil in the prophylaxis of this condition.

Poulsson discusses these results, and attributes the superiority of cod-liver oil in the treatment of human rickets to the fact that it contains vitamin A as well as vitamin D. In experimental work on rats the diet is carefully arranged to contain an adequate amount of vitamin A, and as the bone changes studied are due solely to deficiency of vitamin D, they are readily cured by vitamin D alone. The diet of children of the poorer classes is deficient, however, in all animal fats, and for this reason the condition is more complicated. Cod-liver oil, therefore, which contains both the fat-soluble vitamins, produces better results in children than does irradiated ergosterol, which contains only vitamin D.

A complicating element in the nutritional evaluation of cod-liver oils is the variability of the vitamin content figure. Further complexity is introduced by the fact that the methods of assay of cod-liver oil are in a state of confusion. As regards vitamin D, the method of assay of the Pharmaceutical Society is generally accepted in this country. According to this, one rat unit means an antirachitic action equivalent to 0.0001 mg. of the standard irradiated ergosterol supplied by the Medical Research Council. In Norway, however, Poulsson has adopted a procedure in which the rat unit is less than half the British rat unit. Norwegian methods will therefore give a rat-unit value for cod-liver oil two to four times greater than that given by the British methods. The American Council of Pharmacy and Chemistry has proposed yet another method for measuring vitamin D, in which the unit is about six times the British unit. The value of the rat unit of vitamin D varies, therefore, over a twentyfold range, and the term means very little unless the method adopted is stated.

A report entitled "The relative values of cod-liver oils from various sources" has been prepared by Professors Drummond and Hilditch for the Empire Marketing Board.[3] The chief aim of this investigation was to determine the vitamin content of the cod-liver oils produced in Newfoundland and Scotland, but various other problems are discussed. As regards the estimation of vitamin A, the authors consider that the method adopted by the *United States Pharmacopoeia* is unsatisfactory, and may give indefinitely large errors with oils of exceptionally high and low potency. They show that there is a close correlation between the colorimetric method (blue colour with antimony trichloride) and satisfactory biological tests. Generally the A and D values of oils run parallel, and hence for ordinary purposes the medicinal property of a liver oil is indicated by the relatively simple colorimetric test. Oils from Newfoundland and Iceland have a natural yellow colour which is deeper than those from Norway, but there is, unfortunately, a belief that the colour indicates unsatisfactory technique in extraction. Professors Drummond and Hilditch find, however, that "it is certain that the yellow colour of this product is natural and is associated with a high vitamin activity. The same is true of many Icelandic oils, and of some produced in Scotland. The pale oils derived from the Lofoten fishing are, generally speaking, of low vitamin activity." They have analysed a large number of oils from different sources, and their figures show that, when measured by a uniform standard, the Newfoundland and Icelandic cod-liver oils have a vitamin A content about twice that of the Norwegian oils. The values for Scottish oils occupy an intermediate position.

The report includes details of the methods of manufacture of cod-liver oil in Scotland and in Newfoundland, and it should do much to dissipate a certain prejudice that has arisen from misleading statements about the Newfoundland oil. Incidentally, the authors mention the rather startling statements made by Aghuhr regarding the toxic actions which he claimed were produced on the heart by cod-liver oil. This

work has been criticized by various authors, and Professor Drummond states that in a long experience of administration of cod-liver oil to animals of many species, he has never observed harmful results following the use of reasonable doses. Another point touched on is the frequent adulteration of cod-liver oil for cattle, and the suggestion is made that certain specifications should be adopted for liver oils sold for consumption by farm animals. The authors investigated, also, the vitamin content of the food of the cod. They conclude that the primary source of vitamin A is the minute green plant life of the sea, which directly or indirectly forms the primary food supply of the teeming animal life of the ocean. The source of vitamin D is, however, uncertain, for these plants do not produce it in appreciable quantities, and the small crustacea which comprise the main food of the cod were found to be deficient in both vitamins. While it is difficult to account for the source of the high vitamin content of cod-liver oil, they think it unlikely that the fish synthesize the vitamins, and incline to the belief that these are concentrated from the large bulk of food which the fish consume.

INTERNATIONAL COMPARISONS OF MEDICAL PRACTICE

The Milbank Memorial Fund a few years ago decided to undertake a comparative study of the state of medical matters in the several countries of Europe, which should be mainly concerned with the relationship between the private practitioner and the different national public medical and health services. For such a study there exists an abundance of polemical literature, as well as a mass of official reports and statistics, but few readers have access to them, or possess the collateral knowledge necessary to judge of their significance and permanence. It was decided, therefore, to entrust the study to a single observer, to be given time and facilities to collect his own materials on the spot in each country, and to make his own appreciation of the situation in each. The Foundation was fortunate enough to obtain Sir Arthur Newsholme's acceptance of this task, and the first of four promised volumes of *International Studies*[1] from his pen has now been issued. It relates to the Netherlands, Germany, Denmark, Austria, Sweden, Switzerland, and Norway; the second volume is to cover six other countries, including France, Belgium, and Italy; the third is to be given wholly to the United Kingdom and the Irish Free State, while the fourth will take the form of a general review. The present volume by itself is notable testimony to the courage, and, indeed, if Sir Arthur Newsholme will pardon us, the youthful enthusiasm with which he has undertaken this formidable task.

It would be interesting, but we imagine wholly futile, to pass the medical and public health work of every country in Europe under review, pick out their particular excellencies, or find their greatest common measure, and combine them into some international scheme that could be put before the coming generation as an ideal pattern for medicine and the State which should be followed everywhere. Even the strongest advocates of internationalism and unification would hesitate to go this length. Things being as they are, the medical position in each country, like everything else, must be taken with the national position; there can, for instance, be no understanding or forecasting the future of medicine in Austria without realizing the Treaty of St. Germain, or in Denmark unless it is borne in mind how essentially the economic welfare of that country is bound up with the export of its dairy produce to Great Britain. In all countries the practice of medicine and the medical social service must adjust themselves in the long run to the situation, needs and genius of the nation in which they are exercised, and their progress ought not, in the interests of medicine itself, to be handicapped by artificially created international standards and doctrines. But when all is said, we must remember how often in our own time particular features of medical organization have been taken from one country and adapted in another; our own borrowings from Germany in the creation of national health insurance, and the rapidity with which the establishment of regional "health centres" is spreading from country to country in Eastern Europe, are sufficient reminders of this fact.

There is thus a great benefit in possessing, in convenient form, data which show how any given country has reached its present position, or obtained its special advantages, on the medical side. Sir Arthur Newsholme, in this readable and instructive volume, has done this for each territory reviewed, taking as his principal objectives the medical attendance on the poor, the provision of hospital treatment and consultation facilities for the sick, the medical phase of sickness insurance, the special position of tuberculosis and venereal diseases, and particularly the problems of maternity and child welfare. Those who are visiting the countries with which his book deals would do well to slip it in beside their guide-books if they are likely to be meeting their medical brethren abroad, and comparing notes with them on the politics of medical practice, or on the progress of national, social, and hospital services.

PROPRIETARY MEDICINES BILL

Adequate control, in the public interest, of the traffic in proprietary remedies is a reform long overdue, and any attempt to effect it is sure of the sympathy of the British Medical Association, which has from time to time made its own contribution to the end in view, notably in its early inquiries into various forms of quackery, in the publication by the *British Medical Journal* between 1905 and 1912 of the analyses collected in the books *Secret Remedies* and *More Secret Remedies*, and in its evidence before the Select Committee on Patent Medicines in 1909. The Proprietary Medicines Bill,

introduced by Mr. Somerville Hastings in the House of Commons on Monday (of which our Parliamentary Correspondent gives a brief summary at page 873), and backed by a group which shows no distinction of party and includes several laymen, is of no small interest. Detailed comment on its provisions must be reserved until the full text is available, but it is already possible to say that in our opinion its sponsors are to be congratulated on the production of a measure which, while based on the recommendations of the Select Committee and the Bill introduced for the Coalition Government by Dr. Addison as Minister of Health in 1920, is definitely superior to its models in points of detail. In drafting the Bill they seem to have made full use of all the material available, including the recommendations of the Select Committee, the text of Dr. Addison's Bill, its discussion in the House of Lords and the amendments there introduced, and the suggestions put forward later for the agreed measure which was promised when the Bill was withdrawn and which doubtless adorns to this day some pigeon-hole at the Ministry. They have also kept in mind such modifications in the position as have been introduced by legislation since the issue of the Select Committee's report in 1914.

THE STANDARD ATTAINED BY MIDWIVES IN LONDON

The general standard attained by midwives in London, especially in ante-natal work, is the subject of a report by the Midwives Acts Committee of the London County Council. Comparisons are made with the conditions obtaining in 1909, 1919, and 1929. In 1909 the midwives who notified their intention to practise numbered 537, of whom 103 had been placed on the roll by virtue of having been in "bona fide" practice. These were mostly quite uneducated women, with, however, a certain proficiency in conducting labours. The number who had gained their certificates between 1902, when the first Midwives Act was passed, and 1909 was 213, and the general education of these women was usually poor and their experience limited. The remaining 221 were on the roll in virtue of possession of earlier certificates, such as those of the London Obstetrical Society and Queen Charlotte's, and were the best-educated and most proficient then practising. The usual fees received by midwives in London at this period were 7s. 6d. to 10s. 6d. a case. By 1919 there had been a considerable improvement in the type and education of midwives. Of the 659 who notified their intention to practise, the "bona fide" numbered only 45. Approximately half the 450 midwives who were estimated to be in constant district practice had passed the examination of the Central Midwives Board, and the effects of the increase in the period of training from three to six months enjoined by the Board in 1916 had begun to be felt. Other factors in the improvement were lectures in advanced midwifery by obstetric specialists, the passing of the first Act for the registration of maternity homes, the increased remuneration (usually 15s. to 30s.) a case, and the higher standard of the midwife teacher. In 1929 the number of midwives notifying was 828, and the "bona fide" had been reduced to 9. There had again been marked advance in the intelligence and education of the midwife, the reasons being the Midwives Act, 1918, with its provisions with regard to note-taking and record-keeping, the new rules of the Central Midwives Board, the grant towards the education of pupil midwives, the improvement in the instruction given by the midwife teacher, the extension from six to twelve months of the period of training for the C.M.B. examination, the campaign in regard to the lessening of maternal mortality, an increase in fees generally (which varied now from 16s. to 30s. in East London, and from 30s. to 50s. in West London), and, finally, a growing feeling of professional pride, fostered by increased intercourse between midwives through the Midwives Institute and in other ways. During 1930 the Council received notices of their intention to practise from 901 midwives, of whom 419 were regularly practising. A detailed assessment of the work of these midwives is given in the report to the Council. As to the ante-natal work, this was declared to be good in 251 cases, fair in 90, and poor in 37, while no assessment was possible owing to insufficient data in the remaining 41 cases, making up the 419. The midwifery work was good in 278 cases, fair in 88, and poor in 17. The conclusion of the report is that the standard of a private midwife to-day compared with that of ten years ago is a much higher one, and incomparably higher than that of twenty years ago. Present-day midwives are younger, more alert, better educated, more intelligent, and of broader outlook. In their dealings with one another they have a higher sense of honour and of professional etiquette. The class of women who enter as midwives is principally the lower middle-class and better artisan type, with a sprinkling of more highly educated women, who are probably attracted to the profession by the opportunities it offers for social work. The data for ascertaining whether the newly trained midwife tends to go into an institution rather than enter private practice are insufficient, but on the whole it appears that the better-educated midwives, and those who are trained nurses, are more frequently attached to institutions than to private practice.

TAVISTOCK SQUARE CLINIC

The invitation to the annual luncheon of the Tavistock Square Clinic, which was held at Wharnecliffe Rooms on May 11th, bore the intimation that the clinic is "in process of extension to become the Institute of Medical Psychology." Dr. H. B. Brackenbury, chairman of council of the clinic, speaking at the annual meeting which preceded the luncheon, said that the clinic would be compelled, owing to the falling in of the lease, to vacate its present premises in Tavistock Square before the end of next year, and some other place would have to be found. This would mean increased expenditure and further help from the clinic's friends. It would also be necessary for the clinic to have a new name, and there was now a project that it should take the name of "The Institute of Medical Psychology." The honorary treasurer, Mr. D. O. Malcolm, announced that for the first time in his recollection there was a balance (of £593) on the right side of the income and expenditure account. He also revealed that the occupation of some premises in Bedford Place, quite near Tavistock Square, is being sought. The gathering at luncheon, over which Dr. Brackenbury presided, was addressed by the Countess of Limerick, who said that the clinic had been in existence for just over ten years. It was the pioneer institute of its kind, and during its

short life it had achieved really valuable work, not only on the curative side, but in the research facilities which it had offered, and, not least, in the long-sighted policy of educating a generation of parents in the principles of child psychology. The number of patients had increased from year to year, and that alone was a fine testimonial to the work achieved. Professor William McDougall, F.R.S., also gave a brief address, in the course of which he expressed admiration for the work the clinic had accomplished. It had solved two problems which even ten years ago appeared insoluble—namely, the problem of providing psychiatric treatment for persons of modest means, and that of providing opportunities for the experience and training of persons who desired to make the handling of cases of functional disorder the main part of their life's work. The Tavistock Square Clinic, in these two important matters, had set the pace to the world. He did not believe there was anything comparable in any European country, or even in the United States. He himself had been pessimistic about the possibilities of doing the things which the clinic was now doing, but the faith and optimism of Dr. Crichton-Miller had shown him that he was wrong. He suggested that its new name should carry the word "National" before it, following the example of the National Institute of Industrial Psychology; he did not think anyone would quarrel with such an assumption. Professor McDougall went on to make a reference to Professor Freud, whose doctrines, he said, did not commend themselves to him as adequate, but he joined in a tribute to his personality and work, and he made the suggestion that a message should be sent, congratulating Professor Freud on his seventy-fifth birthday, which he had celebrated a day or two previously. Professor McDougall also described a scheme in connexion with Columbia University whereby special courses were arranged for university graduates (not necessarily medical) in preparation for a diploma in psychology, the idea being that those who held the diploma would assist in the wise adjustment of the difficulties of individuals, from the preventive rather than from the curative or therapeutic point of view. Dr. Crichton-Miller, the honorary director of the clinic, gave a humorous survey of a day's work, taking his audience in imagination from the front door to the attic, and introducing them to the various members of the staff.

CANCER RESEARCH IN HARVARD UNIVERSITY

Investigators under the Cancer Commission of Harvard University have been working during the past year to gain information about the processes of growth and metabolism in health and disease, since it is thought that thereby light may be thrown on the cause and cure of cancer and tumour formation generally, in view of the likelihood that these pathogenic developments are metabolic in origin. In the medical laboratories, under Dr. J. C. Aub, the inorganic salt metabolism of the body is being examined, chiefly with reference to the influence exerted on it by diet and the endocrine glands. The study of the relation of the thyroid glands to calcium metabolism has been continued, and also the interrelationship, in the body, of calcium and magnesium, as well as the localization, in the bones, of lead deposits, an index to the mode of inorganic salt deposition generally. Dr. D. Drury has been investigating the changes in the chemistry of the blood brought about by hepatic insufficiency. There seems to be some relation between calcium metabolism and the secretion of bile, but its nature is not as yet clear. Various kinds of endocrine preparations have been tried in the treatment of tumours, so far without success, and no benefit followed the employment in carcinoma of the high oxygen and carbon dioxide inhalations suggested by Fischer-Wasels. Other lines of research that are being followed include the physiological action of liver extracts on the blood, the toxic effects of benzol in animals, the glycolytic action of malignant tissues on certain glucose derivatives, and the nature of the chemical elements in tumours and in normal tissues. At the Collis P. Huntington Memorial Hospital, which is working in association with the Cancer Commission, groups of cases are being studied, and a report has been published by Dr. Greenough on the valuation of radiation combined with operation in the treatment of cancer of the breast. The better results were obtained in cases which were not submitted to prophylactic radiation.

INVALID CHILDREN'S AID ASSOCIATION

A largely attended meeting to further the work of the Invalid Children's Aid Association was held at Londonderry House, Park Lane, on May 5th, under the chairmanship of Viscount Burnham. The object of the association, Lord Burnham said, was to find a friend for every invalid child in London, and permanently benefit the children by adequate medical treatment and by procuring for them the means of earning a livelihood. During 1930 the total number of cases referred to the association was 16,023, and help was given in as many as 24,134. The children sent to convalescent homes numbered 7,330, while 1,926 were provided with surgical instruments or walking appliances. Lord Burnham emphasized the close co-operation between the association and public bodies. The Dean of Westminster said that it was his privilege to work for some years side by side with Benjamin Broadbent, who did perhaps more than any man in his quiet, unobtrusive way to further a work which at that time was little regarded. The Dean was glad to see the triumph of the voluntary principle as represented in the association, and especially commended the fact that the co-operation of the parents was sought in all the schemes for their children's welfare. Mr. Hugh Walpole spoke of the need of the work in Greater London, among the tenants of the rows of small houses which were extending on every side. He gave a poignant picture of a child of his acquaintance condemned to immobility on an invalid couch. Mr. P. H. Mitchiner said that when he was a house-surgeon in one of the great London hospitals he very soon realized that the work which could be done on behalf of the children was of little avail unless followed up by some system of after-care in the homes, and for this he came to depend largely on the help of the association. Later, as chairman of the North Lambeth branch of the association, he saw to how very large an extent individual interest in the cases was necessary, a method of treatment which could not be forthcoming in a State organization. Mr. Mitchiner added that he had been surprised to find how many families from Lambeth, having migrated to

Dagenham or some new district, presently returned to their old neighbourhood, for the main reason that in the new district they found no hospitals, no visitors from the Invalid Children's Aid Association, and none of the welcome facilities on which they had learned to depend. Sir Humphry Rolleston also spoke in support of the work, emphasizing its value to physicians and surgeons who had to determine what was the matter with the children and what should be done for them. Anyone who had been accustomed to work in an out-patient department, and to see the number of children coming time after time, would confess how difficult it was for him to say why a particular child was "jumpy," or restless, or ailing. The physician could not himself go into the homes of the children, and yet some information about the conditions there was of extreme importance to him. In providing means of information and social amelioration the Invalid Children's Aid Association was doing much to further the preventive ideal of medicine. It was also able to make arrangements for the children to go into convalescent homes. Dame May Whitty also spoke in support of a resolution pledging the meeting to obtain the financial support needed to carry on the increasing work among the invalid and crippled children of the poor, and Sir Charters Symonds and Mr. H. S. Souttar proposed and seconded a vote of thanks to the chairman and speakers, and to Lord and Lady Londonderry, the host and hostess of the afternoon.

RECONSTRUCTION OF THE ROYAL INSTITUTION

The rebuilding of a considerable part of the Royal Institution became imperative some two years ago, after a series of explosions in Albemarle Street, which compelled the attention of the Managers to the dangerous condition of the Lecture Theatre. This historic room, the scene of the Friday evening discourses and experiments of Davy, of Faraday, and of a long line of distinguished scientific men over a period of 130 years, had remained almost unchanged since it was completed under the supervision of the founder of the Institution, Count Rumford, in 1802. It was built entirely of timber, and by modern standards was very ill provided with exits. A survey made two years ago showed the fire risks to be so grave that they could no longer be ignored. Plans were prepared, and a scheme of reconstruction was undertaken. This has now been completed, and a house-warming party was held on the evening of May 6th. The principal consideration in the rebuilding has been to satisfy modern standards of security by means of fireproof construction and by the provision of suitable exits; but the perfection of the design of the Lecture Theatre for the scientific purpose for which it was built has been recognized the world over, and succeeding generations of members have held their meeting room in affectionate regard, so that it has been a particular care to effect the restoration with as little modification of its qualities and appearance as possible. Advantage has naturally been taken of the opportunity to bring the equipment up to date, and the theatre has been provided with a cinematograph projector, an epidiascope, a great variety of services to the lecture table for experimental purposes, and a number of other refinements for the assistance of the lecturer and the convenience of his audience. The rebuilding of the Lecture Theatre has involved the replanning and reconstruction of a large adjacent part of the building. On the ground floor the arrangements have been largely determined by the requirements for exit to the street from the theatre above. A new entrance hall has been constructed, some of the rooms have been replanned, and a large new chemical laboratory has been built. During the evening Sir William Bragg, Fullerian professor of chemistry and director of the laboratory, demonstrated to the guests some of the classical experiments of the Royal Institution.

PUBLIC HEALTH CONGRESS AT FRANKFORT

The Royal Institute of Public Health has drawn up a varied programme for the annual congress, which, as already announced in our columns, is to be held next week at Frankfort-on-Main. Judged by the syllabus, the meeting amounts to a complete mobilization of all the effectives, medical and lay, of the science and art of hygiene. The president of the congress is the Marquess of Reading, supported by an imposing retinue of honorary vice-presidents, including the Primate, peers, politicians, principals of universities, presidents of societies, provosts of burghs, physicians, philosophers, and professors. There are six scientific Sections, dealing respectively with State medicine and municipal hygiene; architecture, housing, and town planning; industrial hygiene; women and children and the public health; tuberculosis; and pathology, bacteriology, and biochemistry. In each the proceedings will last three days, and with such a comprehensive agenda it seems that the delegates will have to make unusual efforts if they intend to amass all the knowledge at their disposal. It is impossible to mention all the subjects, but some idea of the compass of the meeting may be gained by a haphazard selection among the hundred and twenty titles, which vary from "Some new antiseptics," by Dr. F. L. Pyman, to "Pulmonary tuberculosis and marriage," by Dr. S. Vere Pearson; or from "Mothercraft," by Lady Dawson of Penn, to "Das Deutsche Jugendgericht," by Dr. E. Levi. Of topical interest are the papers on the methods of determination of soot and carbonaceous waste gas in the air (Professor Hirsch); health education in industry (Viscount Leverhulme); and State insurance in relation to health (Dr. Brackenbury). In connexion with the congress educational visits will be made to centres of interest in and about Frankfort, and to those famous health resorts of the Rhine district—Wiesbaden, Bad Homburg, and Bad Nauheim.

Two illustrated lectures on Experimental Research at the Pasteur Institute, Coonoor, will be given by Colonel Robert McCarrison, I.M.S., before the Royal College of Surgeons of England, on Monday and Wednesday next (May 18th and 20th) at 5 p.m. The first lecture will deal with surgical aspects of faulty nutrition, and the second with the causation of stone in India.

We have to announce with much regret that Dr. T. R. Glynn, who was for many years professor of medicine in the University of Liverpool, died at St. Asaph on May 12th, at the age of 90.

THE NEW ZEALAND EARTHQUAKE

THE EMERGENCY MEDICAL SERVICE

We have received from Dr. A. C. B. Biggs, medical superintendent of the Napier Hospital, a full account of the emergency measures which were adopted in the recent earthquake in New Zealand, and as the record is likely to be of value in districts where a similar catastrophe may be expected, we print Dr. Biggs's report in an abridged form, as follows.

DAMAGE TO THE HOSPITAL

In this report I shall endeavour to record, as far as possible, the details of what happened and the steps that were taken to deal with the emergency, covering the period of five days from February 3rd to February 7th, occasioned by the earthquake which overcame Napier. The shock occurred precisely at 10.47 a.m., and was of such severity that in less than a minute the whole of Napier Hospital, an institution of 250 beds, was in ruins from one end to the other. The nurses' home, two-thirds of which was a four-storied building, with the secretary's office on the ground floor, completely collapsed, and was simply a piled-up mass of bricks and mortar, this accounting for several of the fatalities in the nursing and clerical staffs. Several wards were very badly shattered, with the walls, however, not completely gone, so that the roofs were more or less held in place. In Robjohns Ward the walls fell in, so that the whole roof crashed to the floor; it was here that a number of patients and nurses were killed. The isolation building, consisting of two wings with a connecting corridor, shared the same fate, the collapse being complete throughout; here again there was loss of life. The "T.B." shelters, being made of wood with an iron roof, showed little or no sign of damage. In the administration block, a two-storied building, there was remarkably little damage; apart from the chimneys, the building stood the shock well, though it was badly shaken and cracked. The whole of the kitchen block, with the domestic quarters above, became a mass of ruins; here two of the kitchen staff were killed. The boiler-house, with all its machinery, and the laundry above, also sustained considerable damage. The mortuary collapsed, but the disinfecting house remained standing. Fortunately the theatre block, underneath which is the bacteriological department, withstood the shock very well, and remained standing. In the *x*-ray department there was considerable damage, but it is thought that most of the plant is recoverable and that it will be fit for use again. The new out-patient department was badly shattered, most of it being in ruins. For all practical purposes the whole hospital was wrecked and put out of action.

RESCUE WORK

Considering the amount of the damage and the sudden onset and rapidity of the disaster, it is astonishing that there were not many more casualties. I attribute this partly to the fact that at that time of day as many patients as possible were out on the verandas of the wards. I want to emphasize that there was a complete absence of panic, both among the patients and the members of the staff; naturally the children were very frightened and the old people in the chronic ward were severely shaken, but nobody seemed to lose his head. The nurses were magnificent, and without a moment's hesitation they were in among the shattered remnants of the wards and the ruins in a brave endeavour to rescue those who had been caught. As soon as the disaster occurred, the first thing to be done was to see that, as far as possible, all patients were out of the buildings, and in this everyone acted spontaneously; the next was to try to ascertain how many unfortunates were buried in the ruins, and to take steps to release them. It was not long before help arrived, in the shape of men with saws, crowbars, etc., and in this connexion men from H.M.S. *Veronica* rendered great service. The work of extrication went forward as rapidly as possible in the hope of rescuing any who were still alive; in the nurses' home these efforts were in some cases rewarded.

THE EMERGENCY SCHEME

Meanwhile a very valuable piece of work had been done in the establishment of an emergency dressing station in the Botanical Gardens beside the hospital; one of the operating tables and all the necessary equipment was taken out of the theatre in the hospital, and within an hour operations were being performed on the badly injured patients who were rapidly congregating at this spot, not only from the hospital, but from the town; other cases were attended to, the place functioning exactly like an advanced dressing station during a war. I may add that all operations were performed with the same surgical technique and aseptic precautions as in normal times, and in no instance was any person operated on without full anaesthesia.

Arrangements were made to take possession of the Napier Park racecourse, four miles away, in order to establish primarily a main dressing station to deal with the immediate needs of the situation; the idea was that it would later develop into a temporary hospital for the whole district. As soon as it was ascertained that the racecourse was available, and that the road to it was still fit for use, a small staff of nurses was dispatched to make preparations. Mattresses and blankets, loaded on all kinds of transport, were sent from the hospital. The organization of the buildings on the racecourse was commenced immediately; the second operating table from the hospital theatre, an emergency light, and all the essential requirements for operating were then collected; these were delivered by lorry to the racecourse, while the casualties were transported by all sorts of vehicles to the same place.

A surgical team was arranged for the work in the improvised theatre; help soon arrived from outside, and very early in the afternoon four operating tables were fully occupied. The house manager obtained a number of tent-flies and small tents, and these were speedily erected on the racecourse, and accommodated the patients after their injuries had been attended to. He also secured sufficient dressings with which to carry on. Adequate food supplies were obtained to cover our immediate needs; a temporary cook-house was erected, and a kitchen range was got going for heating water. All the usual water supply had failed, but in the neighbouring village wells were still functioning, and an inhabitant guaranteed to keep us supplied. Thus all our immediate and essential needs were catered for; work went on apace, continuing late into the night and throughout all the next day.

DIFFICULTIES OVERCOME

The night work continued under considerable difficulty owing to the want of light. We had our own emergency light in one operating room, and in another room illumination was obtained by shining the headlights of a car through the window. Two acetylene burners were procured to light up the big room underneath the grandstand, which was being used as a receiving room for patients.

Fairly early in the evening it was obvious that unless something was done we should be crowded out with patients, as our resources were already being taxed to the utmost. We therefore began to evacuate with our own ambulances, cases being sent in the first place to Palmerston North, a distance of 112 miles; later the medical superintendent of Dannevirke Hospital, eighty-three miles distant, provided some temporary accommodation for our use; cases were then evacuated to it. Messages were sent to the Health Department informing the authorities of this arrangement, and requesting them to arrange a clearing of cases from this point. Meanwhile we had obtained the use of ambulances from other hospital boards as far down as Palmerston North; later others arrived from Wellington.

All through the afternoon and succeeding night doctors and nurses arrived in large numbers from every direction —in fact, so many responded to the call for help that it

was impossible to find work for them to do. Late at night a large party of doctors arrived from Wellington. It was agreed that they could be much more useful further down the line, and they proceeded at once to return to Waipukurau, forty miles away, there to establish a clearing station close to the railway station; this relay post considerably reduced the distance to be traversed by the ambulances. This station was a most valuable help, and worked most successfully until the train service functioned along the whole of the line.

During the course of Tuesday, February 3rd, our staff at the racecourse was steadily increased. Voluntary helpers came along by the score, until by the evening the place was teeming with as many people as would be seen at a race meeting; practically all of them, however, had definite jobs to do, although there were often more volunteers than we could employ.

On Wednesday, personnel and stores were delivered from the Health Department, and later the news arrived that a complete field hospital with equipment was on the way from Trentham. St. John Ambulance men also reported, and rendered great assistance. Cases were steadily streaming in, and it was difficult to maintain an appropriate rate of evacuation. On Wednesday morning, at a meeting in H.M.S. *Veronica*, plans were made to evacuate all casualties by sea to Wellington in the s.s. *Northumberland* and the s.s. *Taranaki*, which were lying off shore in the bay. At midday, however, the evacuation previously arranged by car through the clearing station at Waipukurau had proved so successful that it was decided to continue, and not to change over to sea transport. The ambulance service, however, failed in the afternoon. It appears that the cars were diverted by unauthorized persons for other purposes; thus the organization was seriously upset.

Major Bowerbank and his colleagues relieved me during Wednesday night, and on the following morning took over the task of supervising the erection of the field hospital that had by then arrived. This enabled me to leave the work of the camp in the hands of Dr. Sheppard, who acted for me in my absence; my time was afterwards largely occupied with problems outside, in Napier and Hastings.

Dressing stations had to be established in the town, and arrangements made for staffing and supplies, with a proper ambulance service; communication had also to be effected with the important centres in the town, and with the heads of the various departments. Arrangements were made with the railway officers regarding a rail evacuation that was to commence the next day, Friday, February 6th.

I take this opportunity of expressing my appreciation of the excellent work and organization of the Railway Department in getting trains through to Napier so rapidly, and for their great assistance in the evacuation of patients; the valuable work rendered by the Post and Telegraph Department in the establishment of communications is also to be commended.

CONDITIONS AT HASTINGS

Hastings was visited, and was found to be admirably served by the local medical men, who had established an excellent emergency station in the buildings of the Hastings racecourse. This dressing station was staffed by the medical practitioners of the town, and by Sister Williams and her staff of the Royston Private Hospital, who immediately undertook the task of organizing the medical and nursing services for the whole of Hastings; without their efforts the townspeople there would have been in a very bad way. The chemists and many voluntary workers gave them great assistance. Within three hours everything was established, operations were being performed exactly as in a regular hospital, and all patients carefully attended to in every way. The combined result was one of which they have every reason to be proud. The medical men concerned were Drs. D. A. Bathgate, R. Cashmore, E. Y. Comrie, R. L. A. Kitchen, O. C. Moller, W. Reeve, A. D. S. Whyte, and Romaine Wright. Dr. H. M. Wilson, to his great disappointment, was unable to assist owing to a severe injury sustained at Napier Hospital at the time of the earthquake.

The Memorial Maternity Hospital at Hastings was, fortunately, very little damaged. The staff and patients were all housed in tents in the grounds; the hospital continued to carry on for emergency work, but all maternity patients who could travel further down the line were encouraged to do so.

OTHER ARRANGEMENTS IN NAPIER

The McHardy Maternity Home in Napier had been badly damaged, and vacated; as soon as possible all the cases there were transferred to a marquee set aside for the purpose at the racecourse hospital at Greenmeadows. Other emergencies had been dealt with by the local practitioners in the two parks in the centre of Napier South. These two parks had been rapidly filled with refugees, and emergency dressing stations were established, which did invaluable work.

A further instance of individual initiative is that of Dr. T. Gilray, who rescued all his patients from his private hospital, conveying them and much equipment from his building to Awatoto, three miles away along the seashore, where he got possession of a private house that had received very little damage, and converted it into a small hospital. There, with the able assistance of his own nursing staff and voluntary helpers from outside, he treated many very seriously injured cases from the town, and maintained this service in a most efficient manner for five days.

With the establishment on Thursday of the field hospital at Greenmeadows and the dressing stations in Napier, all medical practitioners in Napier were invited to co-operate in the work to be done. The following responded to the call, and worked loyally and well in the duties allotted to them: Drs. H. H. Barnett, H. Bernau, A. G. Clark, J. J. Edgar, W. D. Fitzgerald, T. Gilray, F. N. Harvey, J. P. D. Leahy, T. C. Moore, R. H. Oulton, J. P. F. Waters, and D. A. C. Will. Drs. G. E. Waterworth and F. Birkinshaw were drafted to assist in Palmerston North, and Dr. S. Scoular was available for any case requiring his special services.

WORK OF THE HEALTH DEPARTMENT

So far I have said very little about the Health Department, but I take the opportunity now of expressing a deep sense of gratitude for the assistance it gave. Experts in all branches, with the necessary personnel and equipment, arrived from Wellington in a very short time after the disaster. These included Dr. Watt (Director-General of Health), with the Hon. Mr. Stallworthy, Dr. McKibbin (the Head of Hygiene and Sanitation), Dr. Shore, Miss Bicknell, Miss Lambie, Miss Moore, Mr. Allen, Mr. Fenton, and Mr. Moore. They all came with the sole desire to help and not to criticize; everything I asked for was given without question, and all took in hand their own jobs with remarkable rapidity and efficiency. In addition to the needs of the hospital, there was the whole town to consider, in particular the water supply and sewerage—a tremendous problem. In all cases the essential services to the hospital were established at an early date, so that the temporary hospital at the racecourse was able by the end of the week (five days from the date of the earthquake) to function in practically the same way as the old hospital had been doing, with full water supply laid on in pipes, and with electric light and power, thus enabling an *x*-ray plant to be installed, for which we are indebted to Dr. Harvey of Napier and to Messrs. Watson and Sons of Wellington.

I consider that the services rendered by the Health Department were perfect; in fact, I am certain that no country in the world could have given a better organized or more efficient service, however much preparation had been made beforehand.

THE HONOUR ROLL

In conclusion, I should like to reiterate my admiration for the courage and devotion displayed by the whole of the hospital staff under my control. They proved once

more that the spirit we are proud to associate with the British race is still present in the highest degree. While all performed their duties so well, I must make special mention of the following:

Sister R. Lowe, who, after a nerve-racking experience in Robjohns Ward, and heroic efforts to rescue her patients, worked almost without ceasing for thirty-six hours at the racecourse hospital; Dr. T. Gilray, for his splendid work in the town; Dr. A. G. Clark and Dr. F. A. B. Sheppard, for their initiative and the very valuable work in the Botanical Gardens on the first day—they were ably assisted in their operations by Sister M. Read and Nurse F. Chesterman; Sister L. Bull and Dr. F. Birkinshaw, for their great help and unceasing labours, also in the Botanical Gardens (Dr. Birkinshaw proved his ability and aptitude later in his organization and work in the refugees' camp in Palmerston North, where he dealt with from 1,200 to 1,500 people); Dr. H. Barnett and Sister M. Wellock, for their work in McLean Park under great difficulties; Dr. Leahy, with the assistance of Dr. Harvey, for the excellent work of the dressing station in the refugees' camp in Nelson Park; Mr. Colvin, the dental surgeon, for his great help in all directions throughout the day, and in particular for his courage in getting the operating tables and other gear out of the hospital theatre and out-patient department.

PREGNANCY DIAGNOSIS STATION

REPORT ON SECOND YEAR'S WORKING

BY

B. P. WIESNER, PH.D.

MACAULAY LABORATORY, DEPARTMENT OF ANIMAL GENETICS, UNIVERSITY OF EDINBURGH

The first report on the working of the Pregnancy Diagnosis Station, which was published in the *Journal*,[1] dealt with the cases diagnosed up to the end of January, 1930. The present report embodies all cases dealt with from February, 1930, up to the end of January, 1931. There was no essential alteration in the organization of the station. It might be mentioned that this report omits all cases that were examined for purely scientific reasons (that is, without a diagnosis being requested); it includes only the results obtained with samples submitted by private practitioners and hospitals. Thus the report does not refer to tumour patients of either sex, etc.; in some of these cases a positive result was obtained although pregnancy could be excluded. The results of the examinations of such cases will be communicated separately as soon as a sufficient number have been collected.

TECHNIQUE OF TEST

Only one change in the standard technique of the test has been introduced. It had been observed by the originators of the test that a considerable percentage of the samples of urine were toxic to the mice, and a similar observation was made in this station during the first year of its working. In consequence of this no result could be returned (during the first year) in twenty-four cases on account of the toxicity of the urine. Since then a method has been published for the detoxication of the urine (Zondek, 1930), but the experience with this method in this station was not quite satisfactory. It has been found, however, that sulphosalicylic acid can serve as a detoxicating agent in most cases. This acid, which acts as a protein precipitant, has been used extensively in the preparation of gonadotropic hormones; it does not precipitate these hormones in the absence of proteins, and removes only small fractions of the hormone from solutions in which proteins are present. The following procedure has been adopted:

To each 25 c.cm. of urine 1 gram of sulphosalicylic acid is added immediately after arrival at the station. The urine is allowed to stand for thirty minutes with occasional shaking. It is then filtered through a paper filter; the filtrate is adjusted with sodium bicarbonate to approximate neutrality (B.D.H. universal indicator—green); it is then used for injection. The same quantities of urine and the same number of mice are used as in the original Aschheim-Zondek reaction.

It has been the practice of the station to ask for a second sample in all cases where the first test did not yield a completely clear result. However, it is doubtful whether this practice will be made a permanent one, since the repetition of tests has, as a rule, not led to much clearer results than are obtained in the first.

The mice used in the station were again procured from a commercial breeder (The Mousery, Rayleigh), and varied in weight from eight to twelve grams. In some cases mice from another source were used; however, they proved to be of a very early maturing, but slowly growing stock. Three errors were due to the use of the latter stock; in these cases a positive result was returned, spontaneous puberty in one or two mice in each of these groups being mistaken for a positive reaction.

RESULTS

In all, 835 cases have been dealt with in the period covered by the report. In 387 cases a negative result was obtained; in 433 cases the diagnosis was positive; in 15 cases the result was either doubtful and we did not obtain a second specimen although it was asked for, or else "no result" was returned because of toxicity of the urine (these latter cases occurred before the introduction of the treatment of the urine with sulphosalicylic acid). Four hundred and fifteen cases have been controlled so far by the clinical diagnosis; in 400 cases the diagnosis as returned by the doctor agreed with the diagnosis given by the station. In 15 cases the clinical and the biological diagnosis differed, thus resulting in an apparent error of 3.25 per cent., as compared with an apparent error of 3.04 per cent. during the first year.

In the first report it was pointed out that the pregnancy test by means of the Aschheim-Zondek reaction represents a test for the presence of a fully functional placenta or of placental derivatives. Therefore a positive reaction is not necessarily proof of the presence of a foetus. It has also been emphasized in the first report that a positive reaction was found in cases of retained adherent fractions of the placenta, incomplete abortion, hydatidiform mole, and chorion-epithelioma. Moreover, the test remains positive for a few days after parturition or abortion, whereas, on the other hand, the presence of a degenerating placenta is not associated with the excretion of gonadotropic hormones. If one examines the fifteen apparent errors from this point of view it is found that in at least two cases the test in reality was correct. In these the error was due to a fault in technique (use of inadequate stock; see above). The percentage of real error is therefore 2.41 per cent.

Among the "apparent errors" there was again a case of a negative diagnosis in the presence of other clinical symptoms of pregnancy, where the foetus proved to be dead and was aborted shortly after the sample of urine had been taken. On the other hand, during the last year a negative test was obtained in three cases where an advanced pregnancy existed (fourth to sixth month) which proceeded normally at least up to the time when the station received the report of the doctor.

While the available evidence is not yet sufficient to draw any definite conclusions, there are nevertheless obvious indications that a negative test returned in cases where the clinical symptoms of pregnancy are present should be of particular interest. Pooling the results of the first and second year one finds twenty-two cases in which a negative Aschheim-Zondek reaction was obtained, while later observations showed that a pregnancy existed at the time; but in at least seven of these cases pregnancy terminated prematurely.

[1] *British Medical Journal*, 1930, ii, 662.

It seems thus advisable to keep under careful observation cases in which a negative diagnosis was returned in spite of the presence of the clinical signs and symptoms of pregnancy, since the prognosis for uneventful termination of pregnancy does not seem to be very favourable in these circumstances.

The station has received, on several occasions, samples of urine taken shortly after an abortion; it was asked whether the abortion could be regarded as complete. However, since normally gonadotropic hormones seem to occur in the urine as long as nine days after complete abortion, the test cannot be of great clinical help before that period has elapsed. Only if samples of urine are found to be positive later than nine days after abortion can it be concluded that placental tissue or derivatives of normal placental tissue are still present in a functional state.

It is also of interest to note that in two cases of very early pregnancy, and in three cases of advanced pregnancy, the test proved originally negative. In two of these cases the test did not become positive until the sixth and the seventh month respectively. If the quantity of hormones excreted in the urine be taken as an indication of the quantity produced, then one must conclude that in many cases where the secretory level is very low, pregnancy ends in abortion whereas in other cases it reaches full term.

EXPERIMENTS IN RAPID TESTING

The originators of the test have shown that in certain cases the time required for the test can be shortened by injection of concentrated urine so that a diagnosis can be made after three days, which is, however, reliable only in cases where the test is positive. The experience of the station with this modification is as yet too small to warrant any judgement. During the last year an attempt has been made to apply certain observations made by Friedmann to the elaboration of a rapid test for pregnancy. This author, basing his experiments on the previous work of Aschheim and Zondek and Hammond, has shown that the intravenous injection of pregnancy urine in rabbits can cause an enlargement of the follicles similar to that which normally occurs after coitus. He suggested that these observations might be made the basis of a pregnancy test. Experiments were carried out during the last year in a number of cases which were at the same time controlled by the standard method. The rabbits were injected with pregnancy urine after it had been deproteinized with sulphosalicylic acid and neutralized with bicarbonate, receiving two to four intravenous injections of three cubic centimetres each within twelve hours. Fourteen to sixteen hours after the first injection the rabbits were killed and examined for ripe and/or haemorrhagic follicles, the presence of the latter was regarded as a "positive reaction." It was found that all urines that gave a negative reaction with the Aschheim-Zondek test also gave a negative result in the case of rabbits. However, some urines that gave a positive reaction in mice did not give a positive rabbit reaction. On informing Dr Aschheim of these experiments we learned that he had attempted similar experiments, but was, like the writer, not yet satisfied as to the possible practical application of the test. Dr. Aschheim demonstrated his experiments at a scientific meeting in Berlin in November, 1930. It is far too early at present to determine the practical value of this test; if it should prove satisfactory it would in many cases reduce very considerably the time required for arriving at a diagnosis (sixteen hours instead of three to five days). Very much more experience is necessary in order to arrive at any conclusion; it is hoped, however, that next year's report will contain results of a greater number of cases tested by this method.

The fees charged by the station are 10s. for tests required by private practitioners and 3s. for tests asked for by hospitals, public health authorities, etc. These fees serve to cover the expenses of the station incurred in the purchase of animals, food, etc. The station will continue its work, being financially secured against deficit by a guarantee from the Medical Research Council.

France

[FROM OUR OWN CORRESPONDENT.]

The B.C.G. Controversy

The question of B.C.G. vaccine has been discussed again in the Academy of Medicine. It seems that the international inquiry into the Lübeck accidents has proved that Professor Calmette's vaccine was not to be blamed, for he cannot be held responsible for the technical mistakes that were made. It is the general principle that has been persistently attacked by Professor Lignieres. The discussion seems as though it would never come to an end, and the learned assembly became somewhat agitated when Professor Vaquez stood up, and to the great relief of the audience, summarized the whole problem in one simple short question: "Are there any circumstances, either experimental or clinical, under which the B.C.G. may recover its virulence?" It was Professor Calmette's opportunity to reply, and he replied with facts. In France 320,000 children have been vaccinated, in Rumania 75,000, in Spain 10,000, in Sweden 5,000, and in the Far East 120,000. About one million cases are on record. Where are the accidents? If an overdose is injected into a calf, or a guinea-pig, the animal develops a fever that might be called "B.C.G.-itis," with polyadenitis, which always ends favourably, leaving the organism immunized against B.C.G. Professor Calmette said that it was time that unfounded apprehensions should be eased, and that insinuations should be stopped. The only way out was for the Academy to set up a commission to investigate all facts and all cases, and to insist that the conclusions, whatever they might be, should be published. A commission, headed by Professor Chauffard, including our most prominent clinicians and scientists, was appointed. It is to be hoped that this official commission will be able to meet the objections raised against Professor Calmette's vaccine by Professor Lignieres of Buenos Aires. It is expected that all doubtful cases will be openly discussed, and that definite conclusions will bring a long controversy to an end.

Antitetanic Serum

The Academy of Medicine was asked to decide in what cases of wounds it was obligatory to use antitetanic serum. A physician was sued for damages because he had not given an injection and the patient died of tetanus. The judgement was against him, and high damages were accorded to the plaintiff. It seems evident that if he had given the serum and the patient had developed peripheral neuritis he would have had the same responsibility to face. A unanimous vote supported the conclusion of Professor Gosset that serum was not to be used in superficial wounds easily cleaned out and in neat cuts not soiled by earth. This seems to leave a beautiful field open to patients, magistrates, and lawyers alike. It may be that prophylactic vaccination with anatoxin, as Professor Carnot suggested, will keep the question out of the courts altogether.

Actions for Malpraxis

It is becoming quite the thing to do—to sue the physician for malpraxis. Over a million francs' damages were claimed from two prominent medical men because they gave blood transfusion too late and the patient died. This time the claim was so manifestly unfounded, and

if admitted would have had such far-reaching consequences, that judgement went for the defendants without debate. This new attitude of the public seems to be the direct result of articles in the lay press, where the whole of medical science is taught within the limits of a column or two. Perhaps the writers of vulgarized medicine (I believe that some of them are qualified men) will understand that it is better for the layman to realize that ours is a difficult art.

Hôpital Beaujon

We hear with satisfaction that the ugly, old, inefficient Hôpital Beaujon, located in the best residential quarter of Paris, is going to be pulled down. It is to be replaced by a new building of eleven stories, with a capacity of over a thousand beds, one-third of which will be in private rooms. It is the first hospital to be built *en hauteur*—the latest hospitals in Paris extend *en surface*. From the descriptions of the proposed building it will resemble the very latest American hospitals as regards both architecture and organization. The new hospital will form a complete unit in itself, the two top flats to be used for open-air and sun cures. It is to be erected in the north-west district of Paris, and it is expected that the difference between the land value of the old and the new sites will be more than enough to meet expenses.

Medical Degrees for Dentists

A new law has been proposed making a medical degree obligatory for the practice of dentistry. At present, what is necessary is a dental school diploma which does not require the passing of a matriculation examination. It seems likely that such a move, for which our medical faculties are unprepared, comes from the fact that there are so many would-be doctors since the war that some new openings must be found for them. The question will be very much discussed in all circles before it goes to Parliament. But at any rate, we all feel that the whole system of medical education will soon be reformed once more.

Scurvy

Dr. Charcot, the well-known Arctic explorer, has come to the conclusion that scurvy is not so much due to the lack of fresh foods as to the use of canned meat. He holds that in cases of incipient scurvy it is essential that this sort of food should be absolutely withdrawn, even when vitamins are abundantly supplied. The consequences of such a theory are so far-reaching that the Secretary of Health has been asked by the Academy of Medicine to take all necessary measures without delay.

G. MONOD.

Ireland

The Dublin Hospitals: A Commission of Inquiry Suggested

Sir William I. de Courcy Wheeler, speaking at the National Children's Hospital annual meeting on May 5th, with Viscount Powerscourt in the chair, said that he was sure, whether the sweepstakes were right or wrong, that charitable people would not withhold their subscriptions so long as the very poor had the first claim on the beds and doctors continued their services without fee or reward. He feared that the hospitals might become dazzled and blind to the needs of the future by the large amounts of money they had recently received, but there should be no reckless expenditure on bricks and mortar. He was proud to think that one of the first actions of the board of the Children's Hospital in dealing out the sweepstake money was to earmark £5,000 for the establishment of an annexe in the country. A modern children's hospital without provision for open-air treatment was a contradiction in terms. It was proposed to make a small beginning, but there was no doubt the open-air hospital would become an important part of the parent institution. The Dublin hospitals should regard the present time as a transition period ; sooner or later complete reorganization was certain to take place. At present there was a hospital in Dublin at the corner of almost every street, each equipping itself to do the same work as its neighbour. This was uneconomic ; the ever-increasing overhead charges were duplicated and re-duplicated. From the point of view of the application of modern medicine and the education of future specialists, the whole system required a thorough overhaul. No university town of similar size adopted the Dublin system, and no young medical man who was seeking more than local reputation in the future or desired to do honour to his medical school would have a chance unless it was changed.

The appointment of a commission to inquire into the Dublin hospital question had been suggested, he thought, by the late Lord Glenavy. After hearing expert evidence and making inquiries into the methods adopted abroad, such a commission would have to recommend an amalgamation of some of the hospitals, or alternatively to allot a special kind of work to each.

Medical Registration Council

The May session of the Irish Free State Medical Registration Council was held at the office of the Council, Upper Fitzwilliam Street, Dublin, on May 5th. The members present were: Dr. D. J. Coffey (president), Dr. A. F. Dixon, Dr. E. Magennie, Dr. James N. Meenan, Dr. H. F. Moore, Dr. T. G. Moorhead, Dr. R. J. Rowlette, Dr. Stephen Shea, and Dr. R. Atkinson Stoney. Correspondence on various matters having been dealt with, Dr. Atkinson Stoney was appointed to the vacancy among the representatives of the Council on the Dental Board. The auditor's report on the accounts of the Council for the year 1930, having been received, was passed for publication with the Irish Free State *Medical Register* for 1931. Procedure was adopted for a visitation of the qualifying examinations.

Public Health in the Irish Free State

The Minister of Local Government and Public Health has addressed a letter to county councils and boards of health in the Irish Free State, emphasizing the necessity for better water supplies and more efficient sanitation. Accompanying each letter is a copy of the Public Health (Special Expenses) Act, 1931, conferring upon county councils and boards of health extended powers for the financing of schemes for the provision or improvement of sewers or sewage disposal, or for the provision and improvement of water supplies in their respective areas. The Minister points out that such provisions, which are very pressing in many areas, have too often been deferred on account of the cost involved, and proceeds to indicate how county councils may secure co-operation between different parts of the county in carrying out appropriate schemes by rendering financial assistance to the boards of health.

Midwives Bill

In proposing the second reading of the Midwives Bill the Minister for Local Government and Public Health explained that as a result of the experience of the Central Midwives Board, to which the regulation of training, practice, and general control of midwives had been transferred by the Act of 1918, the Bill was brought forward to determine more precisely those persons who were entitled to practise midwifery, and to extend the powers under the Board's regulations to prescribe a badge for identification purposes. In practice it had been found that midwifery had been carried out habitually for gain by persons who were not fully qualified. Under the Bill

any such person who attended a woman in childbirth would be guilty of an offence unless the court was satisfied that attention was given in a case of sudden and urgent necessity. Statistics indicated that the mortality of women in childbirth in 1929—namely, 4.1 per 1,000—was the lowest on record in this country. The averages for the ten years 1919-28 was 4.88. This improvement was due to the control of the Central Midwives Board, and to the additional supervision of county medical officers. The Minister stated that the department's policy had been to urge an increase in the fees of midwives whose remuneration was below the average (£52 to £60 per annum). Since the average number of dispensary cases per midwife was only twenty-five a year, there was opportunity for a fair amount of private practice.

Abraham Colles

On May 8th Dr. T. Percy C. Kirkpatrick, honorary lecturer in medical history, Dublin University, delivered an address on Abraham Colles, his life and work, in the School of Physic, Trinity College, Dublin. Colles, he said, was evidently extremely poor during his student years and after graduation, for the many letters he wrote during that period of his life contain frequent references to the cost of food, lodgings, and other items. On one occasion he states that he was charged the exorbitant sum of one shilling for his dinner, but adds that he thinks the price was justified, as the meal was sufficiently satisfying to take the place of both dinner and supper. After studying at the Medical School of Trinity College, where he obtained his diploma in 1795, and later at Edinburgh, he returned to Dublin, and was appointed house-surgeon at Steevens' Hospital, a post which enabled him to engage in private practice and take apprentices. Almost immediately he made his mark as a teacher, and in 1802, being not yet 29 years of age, he was elected President of the Royal College of Surgeons, Ireland. All his life Colles was an indefatigable worker. He had little interest either in social life or in politics. As a surgeon his reputation depended more upon his extraordinary skill in diagnosis and his power of recommending appropriate treatment than on his dexterity as an operator. Although he was never in the front rank of surgeons, his memory has been perpetuated by such familiar terms as Colles's fascia, Colles's fracture, and Colles's law. He was not a voluminous writer, but his communications include an article on the tying of the subclavian artery, an operation which he was the first to perform. In 1830 he was elected President of the Royal College of Surgeons, Ireland, for a second time. He died in 1843.

Scotland

Glasgow Royal Asylum

The one hundred and seventeenth annual report of the Glasgow Royal Asylum, now known as Glasgow Royal Mental Hospital, has just been issued for the year 1930. Dr. D. K. Henderson, physician-superintendent, records that 536 patients were resident in the hospital at the beginning of the year and 555 at its close, while the total number under treatment during the year was 686. Admissions numbered 150, and discharged patients 131, of whom 55 were recovered, 20 greatly improved, and 12 unimproved. There were 54 deaths. Of the admissions, 147 were private cases, and 3 were service patients maintained by the Ministry of Pensions. The increase in the number of admissions during recent years is explained by more difficult economic conditions, greater stress of life, and by the fact that more confidence is now placed in institutions of this type for treatment. Over half the admissions were voluntary patients. The death rate was 7.14 per cent. of the average number resident; of patients who died, 7 had been resident for over seven years and one for forty-five years. The report mentions that there are many patients who are unsuitable for treatment in a mental hospital, and recommends the establishment of clinics or special departments for mental disorders in affiliation with the general hospital systems. These clinics would further provide departments for research and for the education of the medical profession and of the public in regard to the onset of mental illness. Dr. Henderson is of the opinion that too much emphasis is being laid on the mere determination of sanity or insanity, without adequate consideration of the larger social question of disordered conduct, however it may have been caused. Reference is made to the accommodation recently provided by the directors in a nursing home at Darleith, Cardross, where mental patients not sufficiently ill to need treatment in a mental hospital will be admitted without legal formalities. Commenting on the development of the preventive work carred out in a psychiatric out-patient clinic attached to the Western Infirmary, the report states that the special advantages of association with a general hospital have been found to consist in facility of examination, in recognition of the importance of careful study in early mental abnormality, and in the education of students, colleagues, social workers, and nurses. Cases are mentioned of general paralysis treated with malaria, which have shown more favourable results than any previously recorded. The occupational department continued to employ regularly about one-fifth of the total number of patients in the hospital, the male patients being engaged in leather work, basketry, carpentry, metal work, and the female in the making of various kinds of garments.

Dangers to Health from Soot and Smoke

The Scottish branch of the National Smoke Abatement Society held its annual meeting in Dundee on May 6th, under the presidency of Mr. T. G. Fraser, convener of the Public Health Committee. Dr. Elizabeth C. Mudie, who read a paper on coal, smoke, and cancer, said that tables compiled under the auspices of the Cancer Research Institute in London showed that occupations involving the handling and inhalation of soot and tarry products had a high cancer incidence. Domestic soot contained forty times as much tar as that from the factory boiler chimney, and this might explain the relative immunity enjoyed by the primitive races and in the Middle Ages as compared with that of present-day civilization. She considered that it was desirable to abolish the coal fire, which first implanted disease and then by lowering resistance impaired the powers of combating it. Mr. Thomas M. Ashford, smoke inspector, Glasgow, read a paper on the control of industrial smoke. He thought that the solution of the problem of obtaining a pure atmosphere lay in the extensive employment of electricity for power purposes, greater use of mechanical stokers in steam boilers with large plant, and in the substitution of smokeless fuel in furnaces where mechanical stoking was not suitable. In his opinion it would be necessary to bring the furnaces of metal works and domestic sources of pollution under appropriate legislation.

New Professor of Chemistry in Edinburgh

On May 7th the governors of the Heriot Watt College appointed Mr. Thomas Slater Price, D.Sc., F.R.S., to the chair of chemistry in succession to Professor A. Boon. Professor Price is an honours graduate in chemistry and physics of London University. From 1899 till 1903 he was lecturer and demonstrator at Birmingham and Sheffield, and subsequently head of the chemistry department of the Birmingham Technical College. In 1920 he

became director of research of the British Photographic Research Association. During the war he carried out experimental investigations for the Admiralty. At the same meeting it was reported that a tentative agreement had been reached for the affiliation of the Heriot Watt College with Edinburgh University, and that an ordinance was being prepared which would be submitted to the governors of the College and to the University Court. About nine months would elapse, however, before this scheme could become operative.

Central Midwives Board for Scotland

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just concluded, with the following results. Out of 168 candidates who appeared for the examination 154 passed. Of the successful candidates, 70 were trained at the Royal Maternity Hospital, Glasgow ; 22 at the Royal Maternity Hospital, Edinburgh ; 4 at the Maternity Hospital, Aberdeen ; 11 at the Royal Infirmary, Dundee ; 20 at the Elsie Inglis Hospital, Edinburgh ; and the remainder at various recognized institutions.

England and Wales

Medical Women's Federation

The president and council of the Medical Women's Federation held a reception, on May 7th, in the Great Hall of the British Medical Association. Departing from the usual custom of giving a dinner with numerous speeches by eminent men, the Medical Women's Federation struck a new and lively note in entertaining their guests with song, music, and dance, and a tastefully chosen cabaret supper. The Russian Corps de Balalaika, looking very English, played with zeal ; the Mayfair Company of English Dancers charmed and delighted the audience with dances ranging from a minuet to " danse orientale " ; and Myrtle Peter and Miles Arlen gave the company dances that were neither Mayfair nor Russian, but something very pleasantly their own. In her speech, the president, Dr. Louisa Martindale, said that she could not welcome all their distinguished guests individually, but would like to say how proud they were to have with them Dr. T. Watts Eden, Sir Walter Fletcher, Dr. Brackenbury, the Duchess of Atholl, Miss E. Wilkinson, Sir E. Graham-Little, Miss E. Rathbone, Lord Moynihan, Mr. Elmslie, Colonel Samman, Lord and Lady Dickinson, Mr. Goiraud, Mrs. Phillips, Mrs. Highett, and Mrs. Pethick Lawrence. In explaining the *raison d'être* of the Federation, she said that there were fifteen local associations in Scotland, Wales, and England, with a membership of 1,400 women doctors. The work of the Federation was carried out by a council which met twice a year, either in the provinces or London, and by various standing committees, as, for example, on maternity and child welfare and on medical aid for women in India. Representatives from the Federation sat on various public medical bodies. Dr. Martindale drew attention to the work done on cancer of the uterus at the Marie Curie Hospital, which is staffed by women surgeons, and expressed a hope that similar units would in the near future be formed in Great Britain. She mentioned the work of the Federation in connexion with the Medical Women's International Association, the council meetings of which had been held in New York, Geneva, London, Prague, Bologne, and Paris ; this year the meeting would be in Vienna. Dr. Watts-Eden, in a brief speech of acknowledgement, said that he had for many years taught women students and so knew their worth. He hoped that in time the Medical Women's Federation would cease to exist and that the medical profession would be one large happy family in which there would be no need to segregate the sexes. Miss Ellen Wilkinson, M.P., in a hurried visit from the House of Commons, said that medical women had been the bravest pioneers in the women's movement. The speeches over, more music and dancing brought a very enjoyable evening to a close.

London Medical Graduates' Dinner

The annual meeting and dinner of the University of London Medical Graduates' Society was held on May 11th at the Langham Hotel. Sir John Rose Bradford, Bt., presided over a large company, and drew special attention to the fact that the society was honoured by three official guests in the persons of the Vice-Chancellor (Dr. Scott Lidgett), the President of the Royal College of Physicians of London, Lord Dawson of Penn, and the President of the Royal College of Surgeons of England, Lord Moynihan of Leeds, both medical graduates of the University of London, and vice-presidents of the Medical Graduates' Society. It was the first occasion in history that a peer of the realm at one and the same time was President of each of the Royal Colleges, and it might never occur again. All three guests replied to the toast of their health, each being given a great welcome. Among others present were Sir Charlton and Lady Briscoe, Sir Crisp English, Sir Robert Armstrong-Jones, Sir John Atkins, Sir Cuthbert Wallace, Professor Lucas Keene, Professor Elizabeth Eaves, Professor Hey Groves, Miss Catherine Lewis, Mr. W. McAdam Eccles, Mr. Victor Bonney, and Dr. Dorothy Hare and Mr. P. H. Mitchiner (honorary secretaries). The next dinner of the society will be held on November 13th at Bristol.

Treatment of Cancer

Speaking at the annual general meeting of the Cancer Hospital, Fulham Road, S.W., on May 1st, Mr. R. H. Jocelyn Swan said that an elaborate scheme had been organized in the last few years by which every patient who had undergone an operation in that hospital was communicated with and, if possible, presented himself for examination every three months. Radium certainly held a place in the treatment of cancer, but its field of usefulness was being narrowed down to certain forms of cancer in particular organs. The actual attack upon a cancer by burying into it multiple needles each containing a small quantity of radium, so that the whole area could be evenly irradiated, appeared to hold out more promise than the external application, or even that form of treatment supplied by the " bomb " ; and work at the hospital had been carried out on these lines. There was no doubt that the primary growths of the tongue and those in the uterus might in a proportion of cases be made to disappear with radium, but to acclaim this as a cure was misleading. Unfortunately radium did not seem to have such an effect upon the secondary glandular spread, so that in many cases in which the primary growth had been cleared away the secondary growths still continued. A number of cases of cancer of the breast and other organs had been treated with radium with encouraging results, but further time must elapse before they could speak of " cures." It was known that cancer began as a local manifestation, but that migration of cancer cells from the primary tumour gained access to other parts of the body and initiated secondary growths. The whole question turned upon getting cases in the early stages of the disease. At present, except perhaps as regards the tongue, the uterus, and possibly the breast, reliance must be placed on the

orthodox widespread removal of the diseased organ, together with its lymphatic areas of spread. Mr. Jocelyn Swan was of opinion that in radium they had a valuable adjunct to methods of treatment, but it was a dangerous weapon, which should be in the hands only of those who knew how to use it and when to use it, and then used it with the minute care and precision learnt from experience. He thought the time might come when, by the aid of pathologists, it would be possible to differentiate between certain types of cancer—those which were amenable to radium and those best treated by surgical removal.

Socialist Medical Association

The first annual general meeting of the Socialist Medical Association was held in London on May 10th, when Mr. Somerville Hastings, M.P., delivered his presidential address. Speaking of the future of the profession, he said that a knowledge of preventive medicine, which at present occupied a very small place in the curriculum, would become more and more important as the necessity for health propaganda and for a periodical medical examination increased. The medical profession had suffered too long from insulation; the team and not the doctor was the unit of the future. Any doctor working alone in competition with other doctors was apt to degenerate professionally; he became autocratic. Every person who applied for the service of a general practitioner should be provided with it. Mr. Hastings suggested that to every doctor of this class should be allotted about 3,000 persons. Where a hospital existed there should be a medical centre attached in which were situated consulting rooms, so that ante-natal care, child welfare, treatment of tuberculosis and venereal disease, and school clinic work could be carried on in one building. Speaking of hospitals, Mr. Hastings said that all such institutions should be linked together to form a single system; thus, cases could readily be transferred from one hospital to another. There should be a general hospital with a staff of specialists for every county. Dr. Alfred Salter, M.P., said that public prejudice in medical matters would be very difficult to overcome. It would be a long time before the "family doctor idea" could be swept away. Any radical changes must be effected gradually and with the backing of the mass of the people.

The report of the executive committee was approved. It states that although the Socialist Medical Association was formed only in October, 1930, it has already justified its existence; until there is a larger membership, however, it is inadvisable to affiliate with the National Labour Party. One of the principal objects of the association is to devise practical measures for the establishment of a free socialized medical service, and to give effect to this a research subcommittee was appointed to which evidence has been submitted by the British Medical Association and other organizations. An educational subcommittee has also been formed; this body will undertake propaganda work by contributions to socialist newspapers and periodicals, and by lectures to members of the trade union, labour, and co-operative movements. The establishment of territorial branches has begun. The London and Home Counties Branch was instrumental in the production of the pamphlet, *Labour's Hospital Policy for London*, which has had official recognition. It is proposed to send a delegation to the coming international conference of socialist physicians at Carlsbad. Several resolutions opposing charges for treatment at municipal hospitals were agreed to, and the opinion was expressed that municipal and hospital treatment should at once be dissociated from the Poor Law. It was also agreed that the income limit for National Health Insurance purposes ought to be raised to £500 a year.

India

Urban Sanitation

One of the major difficulties in public health administration in India is indicated by Lieut.-Colonel C. A. Gill, I.M.S., Director of Public Health in the Punjab, in his report on the progress made during 1929. He remarks that the view is widely prevalent among the natives that water is the gift of God, or should at any rate be provided free of cost by the Government. The imposition of a water tax, or a water rate, is, consequently, very unpopular, as also is the compulsory attachment of meters to private house supplies, which is held to constitute an undue interference with the liberty of the subject. Water scarcity follows the far too common wilful waste, and it is feared that this state of affairs will continue until municipal committees enforce the model water supply by-laws which have been approved by the Government. No outbreak of disease occurred at any of the religious fairs held during the year, suggesting that the sanitary arrangements and the measures undertaken to protect the food and water supplies of the pilgrims were adequate. Steady progress is being made in providing at Government expense a piped supply of filtered water to localities where important fairs are held annually.

Burmese Medical Institutions

Although the number of hospitals and dispensaries in Burma is considerably lower than is required, it has not been possible to make much headway in building new ones owing to the continued financial stringency and the fact that contributions have been very difficult to obtain locally. However, in his report for 1929, Lieut.-Colonel T. F. Owens, I.M.S., Officiating Inspector-General of Civil Hospitals in that province, is able to announce the completion and occupation of the new Women and Children's Hospital in Mandalay, the construction of a new operation theatre at Ye-U, and the improvement of the civil hospital in Papun. In that year, also, the provision of an operating theatre and *x*-ray block at Mandalay was in active progress, and new wards were being erected in three towns elsewhere. The Rangoon General Hospital treated 86,000 out-patients and 12,500 in-patients during the year under review, although its 535 beds proved quite inadequate to meet the demand. Some relief was obtained by transferring 212 chronic and incurable cases to the Bishop Bigandet Home, but the medical superintendent of the hospital finds even that alleviation insufficient, and urges the necessity of extending the Home so as to receive more of the cases of chronic diseases which are inevitably to be found in a cosmopolitan port. Motor vehicle accidents have risen in five years from 500 to 1,148, and the necessity of dealing promptly with these has proved to be a very heavy strain on the available accommodation. The venereal clinics at several headquarters hospitals in the province have become increasingly popular, but there is still great difficulty in persuading the patients to attend for the full course of treatment. The number of officers of the Indian Medical Service practising in Burma in 1929 was reduced to twenty-one, of whom only fourteen were available to fill the twenty-five appointments reserved for this Service in the Medical Department. The military authorities found themselves unable to release any officers for work in the province, and the depletion of staff seems likely to continue. The shortage of nurses and midwives in district hospitals persisted; it is possible that this will not be remedied until more generous rates of pay can be afforded. The recommendations made

by the special leprosy committee for dealing more effectively with this disease are being considered by the Government, and in the meanwhile these patients have to be dealt with in the various private asylums and clinics. The Pasteur Institute at Rangoon continues to prepare and issue hydnocarpus oil to all hospitals. The new buildings of the Burma Government Medical School were taken over in October, 1929, and Lieut.-Colonel Owens announces the entry of fifty-five new students. The usual course of training in midwifery was given at the Dufferin Hospital.

Madras Government Ophthalmic Hospital

The annual reports of the Government Ophthalmic Hospital in Madras always contain matter of clinical interest, and in the issue for 1929 the superintendent, Lieut.-Colonel R. E. Wright, I.M.S., discusses a large number of local diseases and records various cases. The very severe epidemic of superficial punctate keratitis has continued for a second year, more than 3,500 cases being dealt with up to the end of 1929. The astonishing variability of the symptom-complex, ranging from cases simulating gonorrhoeal infection to others presenting only a slight impairment of sight without other physical abnormalities, has been responsible for some faulty diagnoses. No constant bacterial cause was discovered, but eventually it was shown that the disease was transmissible to rabbits and man, irrespective of whether the material had been filtered or not, and the possibility of some filter-passing virus being concerned, related to that of herpes zoster ophthalmicus and herpes febrilis, is discussed. The pre-auricular gland was enlarged in some cases. Keratomalacia in children is probably the most serious cause of preventable blindness in Madras, as also in Bombay and Bengal and the United Provinces, though it seems to be negligible in the Punjab, where deficiency disease is minimal. More insistence on prophylaxis is required, since the incidence of ophthalmia neonatorum is still too high. Gonorrhoeal conjunctivitis, however, seems to be much less destructive in Madras than in Europe, the individual resistance being higher, or the organism less virulent. The value of adrenaline packs in glaucoma is reiterated; an article emphasizing this form of treatment was published in the *British Medical Journal* of September 7th, 1929 (p. 456). The biochemical examination of the blood in these patients has not been found to be of any special value. Further observations were made on the factors which influence the intraocular pressure during cataract operations after the section has been made. There appeared to be a definite relation between the liability to a low ocular pressure and a sunken orbit, and between an increased intraocular pressure and a bulging orbit, under the conditions of the experiments.

Special Factors Causing Disease

The death rate from tuberculosis in Calcutta in 1929 was 2.6 per 1,000, a slight decrease on previous years. The seasonal incidence was not so marked as might have been expected, but out of the 2,834 deaths, 2,591 were caused by the pulmonary form, surgical tuberculosis being very rare in Bengal, as is bovine tuberculosis. While the disease is largely dependent on such factors as poverty, underfeeding, lack of hygienic precautions, and bad housing, Dr. T. N. Majumdar, health officer of Calcutta, in his report for 1929, calls attention to the serious effects of the custom of early marriages of girls. Five girls die between the ages of 10 and 20 for every boy, and three times as many women as men die from tuberculosis between the ages of 20 and 30. He insists that the most important factor in the etiology of this disease among girls [illegible]women is early marriage, which subjects [illegible]strain of repeated pregnancies and prolonged periods of lactation. [illegible]spiratory diseases were, as usual, more common in the female sex—8.2 as compared with a figure of 5.8 for males per 1,000. Certain ill-drained suburban wards of the city, which are specially liable to flooding, are notorious for their invariably high mortality figures. Overcrowding and want of fresh air are also sadly common. Influenza, however, diminished slightly during the year under review. These suburban areas are still inadequately supplied with sewers; the air, soil, and water are heavily contaminated, and flies are numerous. Much also remains to be done as regards the supply of filtered water to the very poor inhabitants of these parts of the city. Much of the cholera in Calcutta is water-borne, and an increase in the mortality figure for this disease is always noticeable after each of the seven greater bathing festivals of the year; the disease here is limited to Hindus in 90 per cent. of the cases. For the lesser as well as for the main bathing festivals special precautions, such as the opening of a temporary cholera hospital and the provision of pure drinking water, are being adopted, but the death rate from this cause rose in 1929.

Correspondence

SOME TENDON RUPTURES

SIR,—The article on this subject by Mr. Harry Platt, published in the *Journal* of April 11th (p. 611), is, it seems to me, full of sound and interesting suggestions. There are, however, a few comments I should like to make on some of the points raised.

First, with regard to "disinsertion" of the extensor tendon of a finger. When the proximal interphalangeal joint of a finger is flexed the terminal portion of the extensor tendon is relaxed, and the distal joint cannot be actively extended. So far as I am aware, Trotter was the first to apply this fact to the treatment of mallet finger.[1] If the damaged finger, even a few weeks after the injury, is fixed, as Trotter suggested, with the proximal joint flexed and the distal hyperextended, the patient is given an even better chance of recovery than when both these joints are extended, as suggested by Mr. Platt.

With regard to rupture of the proximal long tendon of the biceps humeri in an otherwise normal arm, I see no special advantage in suturing the severed tendon to the short head. Since the tendon cannot be reattached to its normal site above the glenoid, why should it not be fixed to the bicipital groove? If the groove and the tendon are scarified, and the tendon is sutured to the roof of the canal after being turned down over its upper margin, a firm attachment is secured, and the alignment of the muscle belly is not disturbed. This method of dealing with such cases has given results which appear to be entirely satisfactory.

Rupture—or, better, "disinsertion"—of the distal tendon of this muscle, admittedly a very rare injury, I have met with twice. In the first case, operation showed that the tendon, with a somewhat bulbous extremity, had torn away from the bone, leaving the radial tuberosity completely bare, as in Mr. Platt's case. Without considerable paring this tendon would have required a dangerously large tunnel in the radius if Mr. Platt's method of repair had been adopted. The bulbous extremity was held approximately in its correct position by stitches through the fascia over the supinator brevis, while the adjacent margin of the brachialis anticus tendon and the bicipital fascia were made use of for tension sutures. The result appears to have been entirely satisfactory to the

[1] *Transactions of the Royal Society of Medicine*, Clinical Section, 1911, p. 175.

patient, a wood-worker, who states that he is able to "carry on his work as before the accident." He adds, however, that extension, though full when the forearm is pronated, is slightly limited if the forearm is supinated. In this connexion it is interesting to recall that Mackenzie, in his book on *The Action of Muscles* (1918, p. 75), insists that the biceps is essentially a supinator and not a flexor of the elbow. In the second case the injury occurred in rather a curious way. While playing fives and striking at the ball, the patient, apparently quite lightly, just touched his opponent's elbow with the tips of his fingers. A sharp pain shot up the arm to the shoulder, and he was obliged to stop the game. The local signs appear to have been of the slightest, and the true nature of the injury was overlooked. He was not seen by me till over two years later, when his age and other considerations made operative treatment inadvisable. The disability, as regards lifting weights, was still considerable.

The only other point I wish to refer to is the ligamentum patellae. When this tendon is ruptured I believe it is always advisable to reinforce the suture line with a fascial or tendinous graft, while with a patient operated upon a considerable time after the injury a supplementary graft is absolutely essential to success.—I am, etc.,

London, W.1, May 5th. H. A. T. FAIRBANK.

CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION, WITH GLYCOSURIA

SIR,—Dr. E. Tytler Burke's interesting letter published in the *Journal* of May 2nd refers to a case of coronary thrombosis which was under my care during the last two weeks of the patient's fatal illness. My object in recording the case was to draw attention to the association between coronary thrombosis and glycosuria, rather than to discuss the etiology and pathogenesis of coronary disease.

While fully recognizing the syphilitic element in the present case, I purposely refrained from speculating upon the probable histo-pathology of the patient's arterial system. Being unprovided with the means of ascertaining the nature of the microscopical changes in these tissues, I applied to them the intentionally vague term "vascular degeneration." Though I am not so completely unfamiliar with the modern pathology of syphilis as Dr. Burke appears to assume, I should like to have some more detailed information than is provided by the naked-eye appearances of the tissues before attributing a purely syphilitic origin to widespread cardio-vascular changes in an elderly labouring man, exposed to the effects of alcohol, tobacco, and one knows not what other circumstances likely to affect the integrity of the circulatory system.

It seems scarcely fair to say that "a syphilitic etiology . . was neither considered nor acted upon," or that "the modern pathology of syphilis . . . was not taken into consideration." There is not much opportunity for "action" when one is dealing with an old man in the last stages of cardiac failure, and even the most ardent syphilologist would surely hesitate to suggest that the last fortnight of the life of such a patient was a suitable time to apply active antisyphilitic remedies.

I am in complete agreement with Dr. Burke in what he writes regarding Levine's estimate of the role of syphilis in the etiology of coronary thrombosis. I do not think, however, that (in this country, at least) the general tendency to overlook syphilis is so great as Dr. Burke suggests. Indeed, one notices an unfortunate inclination to blame the *Treponema pallidum* for almost any lesion occurring in association with a positive Wassermann reaction, while other etiological factors are apt to be ignored.

Dr. Burke's scheme for the exclusion of a diagnosis of syphilis is difficult to apply in routine clinical work, and its complete validity is still a matter of opinion. His letter is of value for its insistence upon what I would be the last to deny—the important part played by syphilis in the etiology and pathogenesis of coronary thrombosis. His remarks upon the relationship between syphilis and glycosuria open up such a wide field that, from considerations of space, I refrain from commenting upon them.—I am, etc.,

Glasgow, May 4th. NORMAN CRUICKSHANK.

FRACTURES OF THE LONG BONES

SIR,—Mr. McMurray has misread me. In my lecture in your issue of May 2nd I did not contend that Sir Robert Jones suggested that "posture can reduce deformity"—exactly the opposite, and I cannot see that the words I used can have any meaning other than that which I intended them to convey. I refer to "the context" in which Sir Robert specifically states that flexion of the arm without correcting the deformity is insufficient; which surely shows that we are in agreement. Will Mr. McMurray tell me how Sir Robert Jones's views have been in the slightest way distorted by my quotation of "small isolated portions" of his article? I have read it again and can see no wrong deduction, but if Sir Robert Jones thinks that I have in any way misquoted him, I of course offer him a very sincere apology. I do regard flexion as a most important factor (if not the chief) in the production of ischaemic contracture: in truth, it is the combination of flexion with swelling which does the harm.

I can recall only one case of ischaemic contracture in my ward in the last ten years, and as it was well established when I first saw the boy I cannot vouch for its early treatment, but it was said to have been put up at once in full flexion. I have seen some half-dozen others at Examinations, and in none does it appear to me that malposition—that is, failure of reduction—is a marked feature. I cannot agree with those who hold that the chief factor is pressure exerted by the misplaced lower end of the upper fragment, but Sir Robert Jones's statement that he has "not seen or heard of one case where flexion with complete replacement of fracture has been responsible for this condition" must be given due weight in showing that deformity is a factor to be reckoned with.

Of course, my view may exaggerate the influence of flexion, for, as Mr. Slesinger points out, contracture does not occur after dislocation of the elbow in which swelling may be as marked as after fracture, nor does it occur after local injuries of the soft parts; therefore he argues that the fracture is a very important factor. He, in a spirit of kindly criticism, rightly charges me with inconsistency because I urge immobilization in antigravity positions and yet refuse to fix fractures near the elbow in flexion, which is the antigravity position of that joint. I have not met with subsequent loss of flexion after immobilization of the elbow at a right angle.

In his fourth paragraph Mr. McMurray surely "falls into the grave error of misrepresenting the writings of another surgeon" when he states that I am of opinion that "retention after reduction is unnecessary." I feel that this is the unkindest cut of all, for I was compelled to re-read my lecture carefully, and cannot find a single word to support his statement. If he had written "retention *in full flexion* is unnecessary" I would agree.

The fracture which he then uses as an example—the small fragment consisted of a flake of diaphysis, external

epicondyle capitellum, and part of trochlear, and therefore it is a misnomer to speak of it, as Mr. McMurray does, as a separated epiphysis—had a very oblique upper surface running downwards and forwards: Mr. McMurray has no grounds for his surmise that it was transverse. No one disputes that in a supracondylar fracture the line of fracture is not usually transverse, but passes obliquely from in front upwards and backwards.

The whole question turns upon "anatomical reposition": it is my contention that if this is secure "there is no one position and one only in which reduction can be maintained." In other words, it makes no difference to the fracture whether the elbow is flexed to 30 degrees or to 90 degrees or more: the limits being wider the more transverse the fracture.

As Mr. McMurray treats "hundreds of these cases," let him for the next six months deal with every trans- or supra-condylar fracture of the humerus in the way I advocate—namely, reduce it under an anaesthetic on the *x*-ray table, and if and when perfect reduction can be obtained by this means, flex and extend the elbow to estimate the range in which there is no recurrence of deformity—and I shall be glad to know after this experience whether he thinks that my conclusions are justified.—I am, etc.,

London, W., May 12th. C. H. FAGGE.

ACUTE URETHRITIS IN MUMPS

SIR,—Mr. Frank Kidd's letter in your issue of May 9th reminds me of a case I treated a few years ago. A young man who had been having regular coitus with the same woman came to me complaining of a purulent urethritis with enlargement of both testicles, the epididymis being free from swelling. At first sight the condition appeared to be gonorrhoea, but repeated smears of the urethral discharge, and examination of the woman, negatived this diagnosis. Five days after the commencement of the urethritis a swelling developed in the left, and later in the right, parotid.

In view of the testicular enlargement I treated the patient in bed, but I must confess I did not conceive the correct diagnosis until the parotitis had developed. The entire condition cleared up in about two months, with no untoward results.—I am, etc.,

H. A. MORTON WHITBY, M.R.C.S.

Hampstead, N.W., May 11th.

TREATMENT OF SHOCK FOLLOWING STREET ACCIDENTS

SIR,—In a recent number of the *British Medical Journal* the serious effect of moving those injured in street accidents was emphasized. Careful notes of 326 cases of street accidents occurring in the region of Charing Cross Hospital very definitely support this view. It is extremely difficult to put into figures the actual facts, for the various factors are:

1. The severity of the injuries.
2. The time elapsing between the accident and removal to hospital.
3. The time occupied in reaching the hospital.
4. The treatment necessary at the hospital
5. The details of the patient's condition from the time of the accident till being put to bed in hospital.

The following points emerge from an analysis of these cases, taking for purposes of comparison, as far as is possible, cases with similar injuries sustained under similar conditions:

1. The longer the time elapsing between the accident and the arrival of the ambulance the better the patient's condition.

2. Time spent in removal, and the distance covered, appear to have little effect one way or another.

It was sometimes more than a coincidence to hear the ambulance orderly say, "The patient got very bad on being put into the ambulance, but seems a little better now." To appreciate exactly how much removal affected the patient's condition would require the taking of the rate, pressure, and character of the pulse, the respiration rate, and observations on the general condition of the patient, at five-minute intervals. One might suggest as a useful line of research the presence of a medical man on the ambulance, who could take these observations, and I am sure that, were this done, immediate removal of patients to hospital would be less frequent and the prognosis made more favourable. The administration of morphine alone would be a great help.

It is impossible to compare the results of removal to hospital with those of treating patients near the scene of the accident, as I was called out only to six such cases. These, however, I treated by giving an injection of morphine, waiting ten minutes, and then very gently removing them to adjacent premises, and bringing them to hospital only when all shock had passed off. Two had fallen from scaffolding, and one had been badly injured by a tramcar. Their injuries were so severe that the police took the unusual course of sending for a doctor to come to them. Their injuries were at least as severe as many brought straight to hospital, and yet their condition at the end of an hour and a half was better than that of similar patients in hospital after the lapse of that time. Moreover, several medical men working in colliery districts are convinced that delay in removal, whenever possible, is very necessary after mine accidents. The few cases I have seen so treated have recovered far more quickly than similar cases which were removed to hospital immediately. I am convinced that if the London County Council or the London hospitals kept a casualty officer for the purpose of examining and treating the injured at the scene of the accident a very great improvement would result.

One further point. On arrival at the treatment centre there is a very strong temptation to do something at once, such as setting a fracture. The resistance of this temptation is in no wise helped by the pressure brought to bear on the casualty officer by well-meaning, sympathetic relatives, and even nurses. Yet this temptation must be resisted. It is far from gratifying to have set a fracture perfectly only to find it has been done on a dead man.

My routine treatment for cases of shock after admission to hospital varied according to whether the injuries were accompanied by haemorrhage or not. If there was no haemorrhage the patient was put to bed gently, lying flat, and as far as possible removed from external stimuli, and kept very warm with hot-water bottles or an electric cradle. Warmth is most important, owing to the great fall in body temperature. The cradle is preferable to hot-water bottles, on the ground that the type of heat given out is more effective, and that the apparatus is safer. If hot-water bottles are used they must be wrapped up very carefully, as they are apt to burn unconscious patients. A cursory examination was then made, but no detailed examination, such as would disturb the patient, was done. As to the administration of drugs, if the pulse was rapid and irregular, with failing heart, 2 c.cm. of ether, camphor, and olive oil was given; this was not repeated. If stimulants were needed again in such a case, and in those cases where either such rapid stimulation was not required or where the pulse, though rapid and irregular, was not too bad, strychnine and digitaline were used. Ether and camphor in olive oil has a much more rapid and considerable effect, but is very apt to be

followed by a sudden failure, and, moreover, the duration of its action is shorter. The use of stimulants in these cases has to be considered very carefully, for often a sedative, such as morphine given hypodermically, is more effective by its action in resting the heart. Certainly, as soon as the cardiac condition is sufficiently good to support life, morphine in small doses (1/8 to 1/6 grain) is beneficial, and wherever there is the least restlessness it is essential. In the latter case the dose of morphine is that quantity which produces the desired effect; 1/4 grain should be given at first, and repeated every half-hour until the patient is quieted. Where there is weakness in the volume of the pulse, pituitrin 1 to 2 c.cm. hypodermically is extremely good; brandy and glucose in hot coffee is a useful adjunct. In serious cases saline and glucose infusion, or transfusion, is invaluable.

Where there is haemorrhage the bleeding point should be secured as soon as possible, and the treatment subsequently is the same as that outlined above. Where it is impossible to secure the bleeding point the following treatment is usually successful. The nursing treatment is the same as above, with this modification—that the bleeding point, if possible, should be higher than the heart. Morphine is essential in these cases. Haemostatic serum is useless for arterial or venous haemorrhage, but is of great value in haemorrhage from arterioles, venules, and capillaries. Haemoplastin is more effective and more easily administered than the more bulky and cheaper coagulen-Ciba. The effective dose is 2 to 4 c.cm., and this can be repeated in two hours if necessary; further repetition is useless. Whether it is necessary to repeat it or not, a second dose must be given within ten days, to desensitize the patient.

In textbooks one is told never to give stimulants in cases of haemorrhage; and while this statement is true for the majority of instances, there is a type in which they must be administered. Frequently a case is admitted in which, from a combination of shock and haemorrhage, the cardiac exhaustion is out of proportion to the severity of the haemorrhage. Here mild but rapid stimulant will enable the heart to carry on its function without greatly increasing the haemorrhage. Saline and glucose infusion, or blood transfusion, should be used when necessary in bad cases after haemorrhage has been arrested, but not before. If it is used before, the infusion will merely serve as a wash-out for the veins, and the result is deplorable.—I am, etc.,

H. G. BEVAN-PRITCHARD, M.R.C.S., L.R.C.P.,
Formerly Resident Casualty Officer, Charing Cross Hospital, London.

Blantyre, Nyasaland.

SPINAL ANAESTHESIA

SIR,—Spinal anaesthesia may be in the minds of many doctors owing to my article in your current issue (May 9th, p. 785). I should like to say that, since my published series, a death has occurred during an operation for a large carcinoma coli. It was about my three-hundredth case. This postscript is not intended as a warning against the method, but shows that it is not without danger.—I am, etc.,

Clifton, Bristol, May 11th. A. WILFRID ADAMS.

CHOLECYST-GASTROSTOMY

SIR,—We hasten to admit our dereliction of courtesy in not acknowledging two papers of prime importance, which to our minds completely establish the *locus standi* of this type of operation in biliary surgery. We refer to the Arris and Gale Lecture of 1930, by Mr. R. H. O. B. Robinson, who has kindly sent us a reprint of his lecture, and to the article, published in the *Journal* of May 31st, 1930 (p. 1009), by Mr. L. R. Braithwaite. Had these papers been published at the time we did it, we should have approached without any misgiving or trepidation our first cholecyst-gastrostomy, for the case made out by them for the anastomosis operation is convincing, both on experimental and on clinical grounds. If we have not specifically "honoured the physician," and surgeon, and have ascribed to physiologists the discovery of the normal regurgitation of bile into the stomach, it is because of our elastic conception of physiologists as including, for example, surgeons such as those of the Leeds school, who have done so much for the advancement, not only of scientific surgery, but of physiology.—We are, etc.,

HUBERT PHILLIPS,
DONALD ISAAC,
Port Talbot, May 5th. JAMES MACDONALD.

THE CANFIELD OPERATION

SIR,—I am sure that if Dr. Aldington Gibb will try the Canfield operation in an obstinate case he will find that, though "wrong in principle" (whatever that may mean), it is right in practice. It is more difficult than the Caldwell-Luc operation, but in such practised hands as those of Dr. Aldington Gibb this would be no objection.—I am, etc.,

London, W.1, May 11th. JAMES DUNDAS-GRANT.

*** This correspondence is now closed.—ED., *B.M.J.*

THE ARMY MEDICAL SERVICES

SIR,—The Council of the British Medical Association has evidently spared no personal trouble in formulating the procedure that would solve the question of the Army Medical Services. The points that I would accentuate are that the Director-General should be on the Army Council and the branch entirely separate, and secondly, that civil contracts should take the place of warrants that cannot be relied upon.

It is not recognized as it should be that the A.M.S. is a national asset, as well as a department without which the British Army would fall to pieces. This point—that it is of national value—has not heretofore been considered. Yet there is no public service that supervises the lives of the pick of its manhood in the same way, or with the same far-reaching experience of each individual in its charge. From the age of 17 upwards the vast majority of enlisted men remain under surveillance, in one way or another, as reservists or pensioners or invalids, and their whole history is recorded in their medical history sheets, etc. Under such conditions, and with appropriate facilities for research, investigations and records should materially advance professional knowledge. No public service, no public hospitals, possess such opportunities. Even as it is, the A.M.S. has already advanced our general knowledge and added to the well-being of the nation. How much more would it do so if such advancement was recognized as one of its special functions?

This and other arguments lead one to see that the habit of comparing the pay, etc., of the A.M.S. with that of other officers is fallacious. It is all very well to do so in the case of officers who join regimentally, perhaps afterwards moving into a Department. The Army has to teach these officers their work, and in the world outside—at least for many a long year—the regimental officer has no market value. I do not mean in any way to detract from his value as an individual, except that he is untrained for anything at all. On the other hand, the candidate for the A.M.S. is the finished article, who can

earn his living, Army or no Army. It is a fallacy, therefore, to attempt to grade our officers in their pay and promotion by a regimental comparison, and the only utility of rank is that it is necessary within a body in which rank alone is understood.

The Director-General should be on the Army Council for good reasons. One is that when a medical point arises, if he is not present, any catch-penny opinion culled from the evening papers is quite likely to be accepted as gospel; and as for the Adjutant-General, the present mouthpiece of the A.M.S., the Council might as well have the Astronomer Royal! The position is ridiculous. Moreover, what holds good for the Council holds good in every division and brigade, and the total result is that the Army at present does not receive the full value of what is paid —little as it is—on the Army medical vote.

The question of status is very important, because the officers of the A.M.S. carry with them into the Army the intelligent outlook of the medical profession, its keenness, its scientific *flair*, its idea of personal respect. The young man, the bachelor, is full of life and energy, and he fights a gay battle on personal questions; but as the years go *by, every man advancing in life thinks more and more* of the respect in which he and his work are held. So it comes about that when the gaiety of youth has passed, and disillusion follows, officers of the A.M.S. are often only too glad to leave a Service which is treated, they consider, as an excrescence rather than as the invaluable asset that it really is. How many put their sons into it? That is a crucial test of men's views, as there is nothing an old regimental colonel desires more, as a rule, than to see his son carrying on the family name and tradition.

I am old enough, I imagine, to consider the whole question philosophically, and it seems to me that there are fundamental reasons for the periodical set-back from which the R.A.M.C. suffers. One reason is that the spirit of an army and the spirit of medicine are diametrically opposed. One is essentially destructive, the other preservative. It is the antithesis of Siva and Vishnu, to borrow analogy from Hindu mythology. It requires, therefore, a very liberal mind to interweave these opposing forces, and—except in these liberal minds—it becomes difficult to accept proposals which conflict with hereditary ideas.

Another reason is that no great profession accords its true value to the life-work of any other, and perhaps the more a man knows of his own the less he thinks of another. What great surgeon has any use for a mere general? And what great general does not regard the surgeon in similar fashion? Hence one concludes that it requires more than ordinary intelligence, indeed a very advanced and patriotic outlook, for the leaders of any profession to welcome and to foster in their ranks the members of another.

Lying before me is a reprint, in the *British Medical Journal* of February 10th, 1917, of Lord Esher's letter (*Times*, January 3rd), in which he appeals to Lord Derby to [illegible] Army Council by placing upon it the Director-[illegible] Medical Services. Here is one paragraph [illegible]:

"Certainly [illegible] lapsing between the Adjutant-General's branch over the R.A.M.C. [illegible] responsible, not only for the early failure to grip the real factors of the war, but for the hampering conditions under which Sir Alfred Keogh has worked."

The Secretary of State for War has now before him two roads to choose from. He can either continue on the present lines, absolutely deadening to those whose lives are lived in a military machine, or he can take the path that would lead to the Army being served by the pick of the medical profession. There is little doubt which the Army itself would prefer, as there is no branch more popular with the Army than the R.A.M.C.

My ideal of the A.M.S. is that to belong to it should be a *cachet* of real distinction. It should be hard to enter, full of honour and of the pride of recognized work, free from little tricks and slights, absolutely safe in pay, pension, and prospects. Evolution will perhaps bring such a condition about in time, and when it does no one will recommend the A.M.S. more strongly, as a career, than the retired officers of the Corps.—I am, etc.,

London, W., May 2nd. T. M. CORKER, Major-General A.M.S. (ret.).

PUERPERAL SEPSIS

SIR,—Some weeks ago I listened with awe to a leading obstetrician stating his views to the members of our Division of the British Medical Association. He was interesting, he was emphatic, he had no doubt whatever he was right. At the request of one of our members he touched upon puerperal fever. The subject was too big to go into fully, but he said that two things were certain: (1) it was always conveyed to the patient by the hands of the nurse or the doctor; (2) no treatment beyond general nursing was really of any value. I felt crushed, and as I have not been free from cases of puerperal fever, I felt almost criminal.

And now for a remarkable fact which can be supported by ample evidence. On April 25th I attended a primipara who gave birth to a male child. The child was alive, but had a meningocele about the size of a Jaffa orange cut longitudinally. This swelling at the end of the spinal column was septic—very septic—and looked more like a carbuncle oozing pus than an ordinary meningocele. The smell was so offensive that it filled the room and could be noticed downstairs in the kitchen. The sepsis was not that of a few hours, but of at least a few days. Of course, my patient soon became a case of puerperal fever, but fortunately she has recovered.

Now I feel less awe-struck, less crushed, less criminal, for to me this case proves beyond any doubt that organisms can and do invade the gravid uterus and cause sufficient mischief to bring about puerperal fever, and that wholesale condemnation of the doctor and the nurse is unjust, unfair, and untrue.—I am, etc.,

Keelby, Lincs, May 7th. J. H. WARD.

ABERRANT MAMMARY SECRETION

SIR,—For some time at this school a group of workers has been investigating breast milk, from both biochemical and chemical aspects. Up to the present the investigation has been chiefly confined to the study of mammary secretion after parturition. It has now been decided that this investigation should be extended to include secretions occurring before parturition, during menstruation, and other instances of mammary activity. As such cases are infrequent, may we ask the help of your readers in giving us the opportunity of getting into touch with women in whom the breasts become active before parturition, or independently of pregnancy? The clinical side of the work is carried out by Dr. Shiskin, The Beeches, 26, Carisbrooke Road, Walthamstow, E.17, who has personally undertaken to extract all samples for us. To give the minimum amount of trouble to any medical men or women who can help us in this matter, we would ask them to communicate directly with Dr. Shiskin.—I am, etc.,

May 6th. SIBYL T. WIDDOWS, London (Royal Free Hospital) School of Medicine for Women.

IMMUNIZATION AGAINST VACCINIA

SIR,—In their article published in your issue of May 2nd Findlay and Hindle set out to show, among other things, that immunization against vaccinia may be obtained by the injection of a mixture of immune serum and living virus. However legitimate it may be for them to conclude that they have done this from the results of experiments which they do not give in detail, the one experiment of which they do give a protocol does not support their thesis.

In this experiment one rabbit was given inoculations of the immune serum mixed with vaccinia virus, a second was given inoculations of the immune serum alone, and a third was given the living vaccinia virus alone. When these animals were subsequently tested for their immunity to vaccinia the first and second were found to be immune, but the third was still susceptible. The only conclusions which it might be legitimate to draw from this experiment are: (1) that living virus does not confer immunity; (2) that immune serum does confer immunity and is responsible for that produced by the serum-virus mixture. Surely some mistake has been made in the recording of this experiment?—I am, etc.,

Hale Clinical Laboratory, London Hospital, May 3rd. JOHN BLAND.

Obituary

HENRY BRIGHT WEIR, M.A., M.B.

Pathologist, National Hospital for Diseases of the Heart

In the death of Henry Bright Weir, which took place with painful suddenness on May 4th, forensic medicine in London has lost a most valuable exponent. Dr. Weir, who was a Cambridge University and a St. Thomas's man, received his early training in pathology at the latter hospital, where he became Louis Jenner research scholar and assistant director of the clinical laboratories. Later he was attached to the School of Pathology at Charing Cross Hospital, and later still was pathologist at the Heart Hospital, Westmoreland Street, W. He preferred to be known as a morbid anatomist rather than as a pathologist, and it was in the former capacity that I was fortunate enough to secure his services some fifteen years ago. Since that time he has acted as one of my pathologists, the other being Sir Bernard Spilsbury. Dr. Weir was one of the most modest, as one of the most charming of men. His ability was far greater than he would ever be likely to admit. He regarded himself as one who was always learning, and he was ever anxious and ready to learn from others. Whenever Sir Bernard Spilsbury had an exceptionally important or interesting necropsy to perform Weir would love to attend it so that he might study the methods of that well-known and experienced pathologist, and could thus add to his own store of expert knowledge. Since the Coroners Act of 1926 came into force coroners have had the power to dispense with inquests in cases of sudden deaths of unknown cause where a post-mortem examination has revealed a natural death. These examinations are even more important than when inquests were held and evidence was given in open court, and increased responsibility now falls upon the coroner who decides the case, and upon the pathologist who makes the post-mortem examination upon which that decision is founded. Accordingly there has arisen in London a practice, and a very wise one, of having these examinations made by experienced pathologists who, by reason of their training, and with the assistance of their laboratory work, can generally arrive at decisive and reliable results. In this way Dr. Weir performed a very large number of post-mortem examinations for me in Westminster, Lambeth, Battersea, Wandsworth, and, during the past six months, in Paddington and Marylebone. I came to value his services in this way most highly, and to rely upon his reports with complete confidence. They were models of terse yet comprehensive conciseness. Their conclusions were always founded upon convincing premisses, and if ever there was the least doubt as to the actual cause of death Weir would invariably come to me for further information before arriving at a definite conclusion. His work, which may seem highly unpleasant to some people, was of absorbing interest to him, and he often talked of the fascination of setting to work to solve that ever-exciting problem of "What did the man die from?" Ever patient, quiet, and restrained, he was none the less pertinacious to a degree, and, as so often happens with these modest and retiring souls, he was the very exemplar of efficiency. For many months past he had suffered from heart trouble, and he had to contend with that disability whilst endeavouring to carry out his very exacting duties. His patient and dogged determination to work on to the last was beyond all praise, although one cannot but regret now that he did not spare himself more, and yield to the pressing demands for rest which his symptoms so clearly indicated as being urgently necessary. He leaves behind a widow and two young children, and a host of friends, among whom is one who will find it impossible to fill his vacant place adequately, and will ever deplore the loss of a faithful friend and a loyal, helpful, and charming colleague.

S. INGLEBY ODDIE.

J. W. TONKS, M.A., M.D., F.R.C.S.

Surgeon, Chesterfield and North Derbyshire Royal Hospital; Obstetric Surgeon, Chesterfield Maternity Hospital

By the unexpected and untimely death of Mr. J. W. Tonks of Chesterfield another name has been added to the long roll of those who have died as a result of the exercise of their professional duties. He was born in 1888 at Wednesbury, Staffordshire, and was educated at Queen Mary's Grammar School, Walsall, and Caius College, Cambridge. He graduated B.A.Cantab. in 1909 with a first class in the Natural Science Tripos, and proceeding to University College Hospital became M.B., B.Ch., and F.R.C.S. in 1914, and M.A., M.D. in 1925. At University College he took the Fellowes silver medal in surgery and the gold medal in medicine. In 1914 he joined the firm of Sir Josiah and Dr. Arthur Court of Staveley, Derbyshire, a large and busy general practice in a coal and iron district. He entered the Army in the following year, and worked as surgical specialist in Bombay and, later, with the Tenth Burma Division. During this period he was especially commended by the Governor of Burma for services rendered to a wounded officer away in the hills. Tonks travelled seventy-four miles through difficult and dangerous jungle on a pony, taking about thirty hours on the journey, and on his arrival performed a major operation under the most primitive conditions with complete success. On his return to Staveley in 1919 he was almost at once appointed honorary surgeon to the Chesterfield and North Derbyshire Royal Hospital. In that capacity he soon made his mark, and rapidly obtained a leading position in the area as a safe and reliable surgeon.

In 1929 he gave up general practice, and devoted his energies to further consolidating his position and reputation as a consulting surgeon. At the time of his death he was acknowledged as the leading surgical specialist in the district, trusted and admired by his general practitioner colleagues and the community at large. Some years ago he was appointed obstetric surgeon to the Chesterfield

Maternity Hospital, and, quite recently, consulting surgeon to the Derbyshire County Sanatorium at Walton, near Chesterfield. But his interests were by no means confined to his surgical practice. As secretary to the medical staff of the Royal Hospital his gift for organization and his wide vision had full scope, and he was largely responsible for many of the recent developments which have done so much to enhance the prestige of the hospital. To him, chiefly, the officers of the local Division of the British Medical Association looked for advice and help in the changes in hospital methods and management which are being brought about by the Local Government Act of 1929. He took a keen interest in the B.M.A. Hospital Policy. For some years he was a member of the Divisional Executive, and was marked down as the chairman-elect for the ensuing year.

An all-round athlete, he was a good cricketer and golfer up to the last. He once remarked that, with the exception of bowls, he did not know of any game he had not played. Tonks was a man universally liked and respected both for his professional ability and for his charming personality. By his passing North Derbyshire has lost an invaluable servant and the medical profession a loyal and able colleague.

The sudden death of Dr. J. C. TURNBULL, which occurred at Sutton, Surrey, on April 15th, came as a shock to the people of Bury and district. Only two weeks before he had, for health reasons, given up practice and gone to take up an appointment at the headquarters of the South-Western Division of the Ministry of Health. James Cameron Turnbull was a native of Glasgow, and there took the degrees of M.B., Ch.B. in 1900, and M.D. in 1903. He settled in Bury in 1905, where his sterling qualities were soon appreciated. He became president of the Local Panel Committee and of the Bury Division of the British Medical Association. After a long and arduous period of service in the Army he was appointed to the staff of Bury Infirmary, and, as honorary gynaecologist and obstetric surgeon, was closely associated with the recent reorganization of the institution, and especially with the building and equipment of the maternity ward. Dr. Turnbull was a Freemason and past-master of his lodge; he was also a member and past-president of the Palatine Club and the Burns Club. He was a musician of considerable ability, and in a very real sense was a social asset to the town, where the feeling of regret at his departure has been turned into mourning at his early death. He will be remembered by his patients and colleagues as a loyal friend who inspired confidence by his quiet simplicity, and who tempered his strong character with a kindly humour.

Dr. W. H. FENN GODWIN, who died on April 28th at Hampstead, was the only surviving son of Captain John Godwin, R.E., Military Knight of Windsor. He was for some time medical officer at Avonmouth Docks, and then practised for ten years in South London. Broken health necessitated his going abroad, and he took service as ship surgeon in the British India Line. Later he acted as railway medical officer in Madras and Uganda. He then lived for nine years in Java, and had special permission from the then Governor-General to practise among the Chinese. At the outbreak of the war he returned home to England and joined the R.A.M.C., but after two years' service he was invalided out, and went to practise in Western Australia.

The Secretary [illegible]ngland, Ireland, and Wales will hear two roads to choo[illegible]he death, at the age of 32, of Dr. the present lines, FALLON, after a long illness. Dr. lives are lived in [illegible] of Belfast University, and graduated path that would l[illegible] After this he held posts as house- pick of the med[illegible]d Wigan, and resident surgical officer [illegible]g which time he obtained the D.P.H. [illegible]o years he acted as a ship surgeon, and with his lovable and genial personality increased the number of his friends. At the time of his death he was assistant medical officer of health for Bury, and had almost completed a piece of work full of promise and achievement, which he intended to submit as a thesis for the M.D.

Dr. JESSIE LAMB, who died at Bath on May 1st, after an operation, was a member of a well-known missionary family in Yorkshire. She was born at Wheldrake on January 29th, 1877, when her father, the late Canon Benjamin Lamb, was vicar there. It was while their father was at Clapham, Yorkshire, that Dr. Jessie Lamb and her two sisters volunteered to go out as missionaries of the Church of England Zenana Missionary Society. Miss Florence Lamb, who was trained as a nurse at Guy's Hospital, was the victim of a bathing accident in China, after she had served for only eighteen months in the mission field. Miss Maud Lamb is still working at the St. Catherine's Hospital of the Society at Amritsar, Punjab, with which Dr. Jessie Lamb was so prominently connected for twenty years. Dr. Lamb went to India in 1906 on the conclusion of her training at the London School of Medicine for Women, and a period of work at the New Hospital for Women, London, and the Bermondsey Medical Mission. She had graduated M.B.Lond. in 1903. She worked for four years at Tarn Taran before going to Amritsar in 1910. There she helped further to develop a fine work for women and girls especially, which had been begun in 1880. The extent of the work is evident from the fact that last year 15,000 out-patients were treated there. The hospital has 100 beds, and an average of 800 operations are performed annually. Dr. Lamb not only worked indefatigably herself and won the love and gratitude of hundreds of Indian women, but she helped in the training of many Indian doctors and nurses. The value of her services was recognized by the bestowal on her of the Kaiser-i-Hind medal in 1920.

Dr. JAMSHED N. BAHADURJI, who died in London on May 4th at the age of 61, was a very popular and successful Parsi practitioner in Bombay, and held appointments at a number of medical institutions in that city. Besides his professional skill he was a keen sportsman—a good cricketer and tennis player. Owing to failing health he retired from practice and made his home in England during the past few years. He was the son-in-law of Sir Muncherjee Bhownagree, K.C.I.E., formerly M.P. for Bethnal Green.

The following well-known foreign medical men have recently died: Dr. VITTORIO ASCOLI, professor of internal medicine at Rome, and editor of *Il Policlinico*, aged 68; Dr. KARL GRAUPNER, director of the oto-rhino-laryngological clinic of Berlin University, aged 59; Professor PAUL SOMMERFELD, a Berlin bacteriologist, and an authority on the hygiene of milk, aged 61; Professor MARTIN HAUDEK, the Vienna roentgenologist, who has given his name to the niche connected with gastric ulcer, aged 51; and Dr. PACIFICO DIAZ, an eminent Buenos Aires dermatologist.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The General Board of Studies recommends (*a*) that a university lectureship in pharmacology be established in the Faculty of Medicine as from October 1st, 1930; (*b*) that a university demonstratorship be established in the Department of Experimental Psychology as from October 1st, 1931. These recommendations were approved by the Senate on May 9th.

The following Syndicate has been appointed to consider the medical courses and examinations of the University and their relations to courses and examinations for the B.A. degree: the Vice-Chancellor, Professor H. R. Dean, Mr. W. Spens, Sir Humphry Rolleston, Dr. T. S. Hele, Dr. E. D. Adrian, Dr. A. E. Clark-Kennedy, Dr. L. A. Borradaile,

Professor J. T. Wilson, Professor J. Barcroft, Mr. H. Thirkill, and Mr. H. McCombie.

At a congregation held on May 9th the following medical degrees were conferred:

M.D.—H. K. Goadby, A. Sandison, S. E. F. Gooding, W. G. S. Brown.
M.CHIR.—R. W. Butler.
B.CHIR.—V. H. Ellis.

UNIVERSITY OF LONDON

A meeting of the University Court was held on May 7th, when the chairman, Lord Macmillan, presided.

A cordial vote of thanks was accorded to the Rockefeller Foundation for the gift of about £146,000 to the London School of Economics and Political Science for the further expansion of the school, by the erection and equipment of a new library building and the development of the resources of the library, and for improved facilities for research and post-graduate teaching.

It was reported that the late Mr. Clifford B. Edgar, who represented Convocation on the Senate, had bequeathed £4,000 to the London School of Hygiene and Tropical Medicine for the promotion of research.

LONDON HOSPITAL MEDICAL COLLEGE

Lord Macmillan, chairman of the University Court, will distribute the prizes and certificates to students of the London Hospital Medical College on Wednesday, June 24th.

UNIVERSITY OF SHEFFIELD

Dr. T. E. Gumpert has been appointed honorary demonstrator in physiology, and Dr. James Clark, deputy medical officer of health, Sheffield, has been appointed demonstrator in public health.

QUEEN'S UNIVERSITY, BELFAST

The Senate has resolved that the honorary degree of D.Sc. shall be conferred on Dame Louise McIlroy, M.D., professor of obstetrics and gynaecology, London (Royal Free Hospital) School of Medicine for Women, University of London; on Joseph Barcroft, M.A., F.R.S., professor of physiology, University of Cambridge; on Major-General J. W. D. Megaw, Director-General I.M.S., and on H. Hampton Young, M.D., clinical professor of urology, Johns Hopkins University Medical Department, Baltimore.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Diplomas of L.R.C.P. were conferred on May 7th on the following fifty-eight candidates (including eight *women*), who have passed the requisite examinations and have complied with the by-laws:

Margaret Abernethy, R. E. Adam, Margaret H. Banks, G. Barwell, J. S. Batchelor, R. J. V. Battle, Jessie G. Belilios, L. P. B. Chamberlain, S. C. Cimmering, G. T. Cook, Khorshed M. Cooper, G. J. Cunningham, L. E. A. Dearberg, W. De Lacey, S. D. de Silva, N. B. Fadia, L. Farris, A. C. Frazer, W. G. Glassco, T. N. Gledhill, H. Goldenberg, D. G. Gower, L. J. Hackett, Kathleen M. L. Hall, H. T. Halper, M. Halpérine, A. C. Hauptfleisch, N. Heath, G. Holroyd, J. H. Hunt, A. L. Jacobs, C. D. P. Jones, M. S. Khan, Janet Y. Laidlaw, M. M. Landau, R. C. Langford, G. F. Lashmore, A. J. D. Lewis, H. M. List, A. W. Littlewood, B. F. Longbotham, A. P. McEldowney, G. B. Malone-Lee, T. P. Mulcahy, B. S. Nanjiani, J. L. Parker, J. Ross, Eileen M. M. Shaw, H. J. Shorvon, M. Shorvon, E. G. Sibley, J. H. Spence, A. L. Thomas, J. C. Wharton, Eva M. M. Willett, G. M. Willey, O. S. M. Williams, W. G. Wright.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on May 5th, when the president, Sir Norman Walker, was in the chair.

Dr. Thomas Ferguson (Falkirk), Dr. Ronald Douglas Mackenzie (Edinburgh), Dr. Ernest Watt (Edinburgh), and Dr. George Matheson Cullen (Edinburgh) were introduced, and took their seats as Fellows of the College.

Dr. George Hector Percival (Edinburgh), Dr. David Lees (Edinburgh), Dr. Margaret Black Martin (Edinburgh), and Dr. Joseph Ryland Whitaker (Edinburgh) were elected Fellows of the College.

Dr. Robert Thin was re-elected a representative of the College on the Conjoint Committee of Management of the Triple Qualification.

The Freeland Barbour Fellowship was awarded to Robert Henry Slater, B.Sc., Ph.D.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—*Medicine:* T. A. M. Ashforth, S. R. Ayengar, H. F. Ezzat, S. Grasse, W. Kelly, G. D. Morgan, P. A. P. V. Pillai, M. Smellie, J. A. Walsh. *Surgery:* T. A. M. Ashforth, H. F. Ezzat, A. J. Ritchie, A. G. Williams. *Midwifery:* S. R. Ayengar, S. Grasse, L. Lambinson, H. S. M. Maxwell, M. A. Perera, P. A. P. V. Pillai. *Medical Jurisprudence and Public Health:* M. A. Abdalla, A. E. Albuquerque, D. K. Cowan, E. T. Dietrich, L. F. Donnan, P. C. Dutt, M. O. Luck, A. A. M'Nish, M. J. Moynihan, Alice J. Paton, J. C. H. Speirs, O. Springer, A. M. C. Stephenson, W. B. Taylor, V. S. Trivedi, M. L. Varma, R. F. K. Webster.

Out of eighty-one who entered, the following successful candidates were admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.S.Glas.:

L. Ahmed, P. M. Ballantyne, P. Barron, D. A. Black, J. S. F. Botha, J. Boyle, R. Bulman, P. Dass, A. C. Devaraj, A. Fazary, J. T. M. Fenton-Fyffe, K. Graftdyk, D. M. I. Harmar, M. D. D. Jayawardana, S. G. A. Malek, R. E. Mullarky, Alexandrina M. M. Parker, W. R. Parker, G. S. Robertson, J. Rosenberg, G. Rosenbleitt, M. Sarkar, D. W. Semmens, A. Shaheen, J. A. Shehid, J. E. Sprunt, Helen V. Tindal, H. F. Tindal, A. W. Turnbull, Mary T. Wilson, W. R. Young.

The following, having passed the examinations, have been admitted Diplomates in Public Health:

N. W. Ahin, Helena E. Barrett, A. D. Gorman, B. N. Khan, Mary L. Liston, F. F. Main.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

This week the House of Commons discussed Indian affairs, airships, and overseas trade, and also completed the committee stage of the Representation of the People Bill.

On May 12th the Parliamentary Medical Committee, with Dr. Salter in the chair, heard a statement by Mr. Melluish and Mr. Linstead, president and secretary of the Pharmaceutical Society, upon the Pharmacy and Poisons Bill, which was down for second reading in the Commons on May 15th. These visitors discussed the amendments which they wished to see in the Bill. The first was that in any open shop in which medicines were dispensed there should be at least one qualified pharmacist in charge. The second was that permission to sell "Class Two" poisons should not be given to all who applied for it, but that the local authority should have power of restriction or refusal, having regard to the needs of the locality as well as to suitability of applicant and premises. The general feeling of the meeting is reported to have been that the Bill was useful, but would be improved by these suggested amendments.

The Consultative Committee on Health and Housing heard, on May 12th, a deputation from the Pharmaceutical Society, the Retail Pharmacists' Union, and the "Pharmacists' National Opposition," who stated objections to the Pharmacy and Poisons Bill. The main contention of the deputation was that control of the sale of poisons should not be handed over to the Poisons Board, but be left with the Pharmaceutical Society. A committee of the Liberal party also considered the same Bill, and decided that it would require amendment after second reading.

Sir Leonard Hill has promised that, on June 9th, he will discuss the ventilation of the House of Commons at an open meeting of M.P.'s, arranged by the Parliamentary Medical Committee.

Proprietary Medicines Bill

On May 11th Mr. SOMERVILLE HASTINGS presented the Proprietary Medicines Bill "to regulate the manufacture, sale, and advertisement of certain medicines and surgical appliances, and for purposes connected therewith." The Bill was formally read a first time and set down for second

reading on May 20th. It is backed by Dr. Fremantle, Dr. Morris-Jones, Dr. Salter, Mr. Tinne, Mr. T. B. Wilson Ramsay, and Mr. G. H. Oliver.

The Bill proposes to prohibit the sale of any proprietary medicine or proprietary medical appliance unless (*a*) the vendor is registered as owner of the medicine or appliance, or is a person authorized by the owner to manufacture; also unless (*b*) the medicine or appliance is duly registered as the Bill provides; and unless (*c*) in the case of a medicine it is compounded of the ingredients and in the proportions specified in the register, or in the case of an appliance corresponds with a specimen furnished to the registrar.

The Bill is a long one. It prohibits correspondence offering treatment, and publication of misleading or false testimonials, or of assertions that a medicine or appliance is recommended by an unidentified medical practitioner or was introduced by one. The Minister is to keep a register of owners, of medicines, and of appliances, and make regulations for this purpose. Only the Minister can take proceedings against persons preparing for sale a proprietary medicine compounded of other ingredients, or in other proportions, than those specified in the register.

After six months from the coming into force of the Act sale and advertisement will be illegal in the case of remedies or appliances for deafness, rupture, cancer, consumption, lupus, fits, epilepsy, amenorrhoea and other diseases peculiar to women, diabetes, paralysis, locomotor ataxia, or Bright's disease. There is an absolute prohibition of advertisements suggesting the use of articles for abortion, miscarriage, or the cure of sexual weakness.

No opportunity will occur for the passage of the Bill this session.

Income Tax

On May 7th the House of Commons considered the Budget resolution which provides that, on January 1st, three-quarters of the income tax due for the year shall become payable, instead of one-half as at present. Mr. C. WILLIAMS moved an amendment providing that, instead of three-quarters, seven-twelfths of the total sum due should be payable. Dr. ELLIOT, in supporting the amendment, took the case of a doctor, going on year after year, with a large panel practice. Such a man earned a considerable sum, but he could not go on for ever. These proposals would fall hardly on the panel doctor, working long hours and looking forward at a relatively early date to getting away from the heavy hammer of an industrial practice into some country practice, where his income would be very much less, but where his health might be expected to last a good deal longer. The panel doctor in a colliery district worked under a strain from which he frequently broke down. Such a man earned every penny he got, and when the question of a reduction in panel fees was being considered the representatives of the workers often stood out against any proposal for reduction. Mr. W. GRAHAM resisted the amendment, which was defeated by 255 votes to 156. Mr. Hastings, Dr. Hunter, Dr. Drummond Shiels, Dr. Salter, and Dr. Morris-Jones voted against the amendment, which was supported in the division lobby by Dr. Elliot and Dr. Fremantle.

Silicosis

Mr. CLYNES told Mr. Train, on May 7th, that under the Sandstone Industry Silicosis Scheme, 1929, claims had been made in Scotland on the fund for one case of death and two of partial incapacity. The first periodic medical examinations would not be completed for some time. Thereafter the rates of levy paid by quarry masters would be reviewed.

Answering Mr. Rennie Smith on May 7th, Mr. CLYNES said the international classification of the stages of silicosis and their radiological diagnosis, which was mentioned in the report of the International Silicosis Conference of 1930, had been adopted by the conference. Having regard to the character of the conference this classification was universally accepted. The conference [illegible] should institute researches into [illegible] disease due to dust, and [illegible] Industrial Fatigue Research Board [illegible] by the Medical Research Council to investigate silicosis and other forms of pulmonary disease. Schemes of research drawn up by this committee had been approved and were being put into operation. The protection of factory workers against exposure to dust had for many years received attention from the Home Office. The special provisions in codes of regulations for dusty industries were constantly under review. The preventive measures recommended by the International Silicosis Conference were based on those actually adopted and applied in Great Britain.

the present [illegible] officer
lives are lived in [illegible] search
path that would [illegible] After [illegible]
pick of the med[illegible]d Wigan, and resident[illegible]
[illegible]g which time he obtained the D.P.H. [illegible]
[illegible]o years he acted as a ship surgeon

Animal Experiments

Mr. FREEMAN, on May 5th, asked the Home Secretary whether the 131 experiments involving 719 living animals recorded by the Chemical Defence Experimental Station, Porton, during 1930, were recorded in the annual official report of the Home Office as 719 experiments, or, if not, how were they recorded. Mr. CLYNES replied that in this case the number of experiments recorded in the annual return would be greater than 719. The precise figures were not yet available. In some of the cases it was necessary, after the initial procedure, to withdraw a small quantity of blood for examination, and each such withdrawal was treated, for statistical purposes, as a separate experiment. As there were a few returns from licensees still outstanding, the final figures of experiments on living animals in 1930 could not yet be given. It was not expected, however, that they would make a material difference to the total. The available returns showed that 450,744 experiments were performed under the Act during 1930, of which 432,474 were without anaesthetics and 18,270 with anaesthetics. The number performed for cancer research was 25,259, of which 23,964 were without anaesthetics and 1,295 with anaesthetics.

Milk for Schools

In reply to Mr. R. S. Young, on May 6th, Mr. MORGAN JONES said the Board of Education was co-operating with the National Milk Publicity Council, and every opportunity was taken to bring to the attention of local education authorities and teachers the council's scheme for voluntary milk clubs in schools. The National Milk Publicity Council stated that this year they provided milk for 600,000 children, as compared with 350,000 last year.

Answering Mr. Freeman, on May 7th, Mr. LEES-SMITH said he had the power, by compulsion either on education authorities or on parents, to secure that every child in school received a daily supply of fresh milk. He was encouraging such provision.

Traffic Privileges for Doctors

Replying to Mr. Marjoribanks, on May 6th, Mr. HERBERT MORRISON reaffirmed his opinion that the authorization of special signs, horns, or lights on the cars of medical practitioners to give them facilities through traffic in cases of emergency would involve serious interference with the free flow of traffic. Mr. MARJORIBANKS asked that consideration should be given to a system adopted in Canada, which worked well. Mr. MORRISON said he had carefully considered the matter.

Funds for Cancer Research

On May 12th Mr. GREENWOOD told Mr. Freeman that he had no funds at his disposal for making grants to the Imperial Cancer Research Fund and the British Empire Cancer Research Fund. *Information* was not available in his department of the extent to which contributions might have been made to these institutions out of local funds. Any part of the inclusive grant in aid received by the Medical Research Council from the Exchequer might, at its discretion, be allocated to work on cancer, and certain expenditure on the investigation of this subject through a departmental committee was borne on the vote for his Department. He had no information as to any similar expenditure out of local funds.

Vaccination and Small-pox

On May 12th Mr. GREENWOOD told Mr. Freeman that six deaths were registered in 1930 in which vaccination, vaccinia, or post-vaccinal encephalitis was mentioned on the death

certificates. Vaccination was mentioned on the death certificates of all those persons, and their ages were 5 months, 3 years, 4 years, 10 years, 19 years, and 71 years.

Mr. GREENWOOD, on May 12th, also told Mr. Freeman that there were thirty deaths in England and Wales in 1930 in which small-pox was certified as a cause of death. In twenty-six of these some other disease was also mentioned on the death certificate. The ages of those who died from small-pox alone were: 13 days, 3 weeks, 9 years, and 33 years. The ages of those on whose certificates small-pox and other diseases were mentioned were: 18 days, 1 month, 7 weeks, 8 months (2), 5 years, 10 years, 11 years (2), 13 years, 16 years, 45 years, 46 years, 47 years, 50 years, 55 years, 56 years, 58 years, 59 years, 63 years, 66 years (2), 69 years (2), 77 years, and 82 years.

Rejection of Recruits.—Answering Mr. Cecil Wilson, on April 28th, Mr. SHAW said that, in 1909, 46.7 per cent. of the men served with recruiting notice papers for the British Army were rejected. In 1926 the proportion was 58.7 per cent.; in 1927 60.1 per cent.; in 1928 57.3 per cent.; in 1929 54.4 per cent.; in 1930 53.1 per cent. Mr. Shaw also stated that in 1930 54.5 per cent. of recruits were rejected in the London zone. In the other zones the proportion ranged from 70.8 per cent. in the East Lancashire zone to 12.5 per cent. in the North Midland.

Purity of Flour.—Mr. GREENWOOD stated, on April 30th, in reply to Mr. Lees, that the view of the Departmental Committee on the Treatment of Flour with Chemical Substances was that most of the substances known in the baking trade as improvers were unobjectionable on grounds of public health in the quantities in which they were used, but they expressed the opinion that the use of chlorine and nitrogen trichloride was undesirable. The committee did not accept the view that so-called improvers generally enabled the flour to absorb more water.

Camphor and the Budget.—In the House of Commons, on May 5th, during a debate about the increased duty on hydrocarbon oils, Commander KENWORTHY moved to exempt white spirit and turpentine. Sir GEORGE HAMILTON pointed out that synthetic camphor was dependent on turpentine. The proposed tax would increase the cost per hundredweight of camphor by 12s. 4d. Camphor had usually come from Formosa, but its synthetic manufacture in Britain began a few years ago, and was now carried on at Ilford and in Essex. Mr. GRAHAM, in reply, said that, as no turpentine remained in the finished product, there was perhaps a case for the application, but he was obliged to stand by the proposal of the Government.

Ophthalmic Benefit.—Mr. GREENWOOD, on May 5th, told Mr White that the total amount spent by approved societies and branches in England on ophthalmic benefit during 1928 was £276,600; in 1929 it was £278,200; and in 1930 £353,300. These sums included payments for ophthalmic examinations and ophthalmic treatment, but the greater portion of them was spent on the provision of glasses. No information was available to show the amounts paid to particular opticians.

Dangers of the Strait-jacket.—On May 5th Mr. BROCKWAY asked the Minister of Health if his attention had been drawn to the case of David Fyfe, who died in Waterloo House, Bethnal Green, with eleven broken ribs, sustained during his detention and following restraint in a strait-jacket; and if he would make an inquiry into the case. Miss LAWRENCE replied that the Minister of Health had already caused inquiry to be made into the case, but this inquiry was not complete. Mr BROCKWAY asked that, in view of the extraordinary nature of this case, two points should be specially borne in mind in the inquiry. The first was, whether there was any padded room in this establishment where a person under detention could be placed, rather than in a strait-jacket; and in the second, whether Councillor Blackater, J.P., would be examined before the inquiry was concluded. Miss LAWRENCE said that the Minister of Health would be glad to consider any relevant consideration, but she warned the House against taking it for granted that the circumstances were as stated in the question.

Mental Deficiency Statistics.—Miss LAWRENCE, on May 11th, informed Mr. G. Macdonald that statistics on the number of persons in England and Wales certifiable as mental defectives were not available. The persons detained on certificates under the Mental Deficiency Acts on December 31st in each of the last five years were: 1926, 20,091; 1927, 21,598; 1928, 23,275; 1929, 25,076; and 1930, 27,811.

Fat from Sewage.—On May 11th Mr. McELWEE asked Miss Lawrence if the Minister of Health would inquire as to the amount of fat that was extracted from sewage disposal works, and whether the fat was being used in the manufacture of margarine. Miss LAWRENCE said that if Mr. McElwee could send her any information as to this practice she would be glad to receive it. At present there was no information. Mr. McELWEE said he understood that a large dairy company was taking several tons a week.

Mortality of Tuberculous Pensioners.—Mr. ROBERTS, on May 11th, told Mr. Hore-Belisha that he could not state precisely the number of disabled officers and men pensioned for tuberculosis whose cases had been reviewed in 1928, 1929, and 1930. The deaths of tuberculous pensioners reported in 1928 were 1,450; in 1929, 1,400; and in 1930, 1,050; but the number of those cases in which death was due to the disability could not be stated.

Invaliding out of the Navy.—Mr. ALEXANDER, in reply to Sir Bertram Falle, said he could not agree that there was any need to issue further instructions regarding the procedure of invaliding men from the Navy, nor for the appointment of any committee of inquiry. Men invalided had adequate facilities for making representations if they felt dissatisfied.

Notes in Brief

An interim report has been made by the Ministry of Health committee which is examining the reports of regional planning committees.

The report of the Government actuary upon the superannuation of asylum officers will be published in a few weeks' time.

The number of women in Great Britain contributing for national health insurance on December 31st, 1930, was 5,750,000.

Medical News

The next session of the General Medical Council will commence on Tuesday, June 2nd, at 2 p.m., when the President, Sir Donald MacAlister, Bt., M.D., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

The next meeting of the Biochemical Society will be held in the Department of Biochemistry, University of Oxford, to-day (Saturday, May 16th) at 2.30 p.m.

A quarterly meeting of the Medico-Psychological Association will be held at B.M.A. House, Tavistock Square, W.C., on Thursday, May 21st, at 2.30 p.m. Papers will be read by Dr. Norman Phillips on mental disorders associated with pernicious anaemia, by Dr. W. F. Samuels on antimalarial work at the Central Mental Hospital, Tanjong, F.M.S., and by Dr. A. Geoffrey Shera on terminal uraemia, with notes on the prevalence of renal disease among the insane. A dinner to commemorate Sir James Crichton-Browne's long and distinguished service to psychological medicine will be held at the Langham Hotel, Portland Place, W.1, in the evening, at 7.30 p.m.

The Royal Sanitary Institute will hold a sessional meeting on Friday, May 29th, in the Guildhall, Exeter, when a paper on the Exeter new sewage purification works will be read by Mr. E. J. Silcock. The chair will be taken at 4.30 p.m. by Dr. Charles Porter.

A meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, on Wednesday, May 20th, at 5 for 5.30 p.m. The papers to be read and discussed include one by Dr. C. A. Hoare on transmission of trypanosomes by insects.

The thirty-second annual meeting of the Lebanon Hospital for Mental Diseases, Asfuriyeh, near Beirut, Syria, will be held on Tuesday, May 19th, at 3.15 p.m., at Friends House, Euston Road, N.W. (opposite Euston Station), under the chairmanship of the Right Rev. Herbert Bury, D.D. The speakers will include Dr. E. W. G. Masterman, chairman of the general committee, and Dr. J. Tylor Fox.

The Inter-State Post-Graduate Assembly of North America will visit London on Tuesday and Wednesday, May 26th and 27th. The following lectures will be given at 1, Wimpole Street: Tuesday morning, "Some medical hints," by Sir Thomas Horder, Bt.; "Some points on the treatment of head injuries," by Mr. Donald Armour; "The myocardium, with special reference to the right ventricle," by Dr. J. Strickland Goodall. Wednesday morning, "Cancer of the rectum" and cinematograph demonstration of the abdomino-perineal operation, by Mr. A. Lawrence Abel; "A gynaecological talk," by Mr. Victor Bonney. Visits will be paid on Tuesday afternoon to the Middlesex Hospital, the Chelsea Hospital for Women, and the Infants Hospital, and on Wednesday afternoon to the London Temperance Hospital, and the National Heart Hospital.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found at page 196 of the *Supplement*. It will be seen that the special evening lectures to candidates for the M.R.C.P. are being continued. A course in gynaecology will be given at the Chelsea Hospital for Women from June 1st to 12th; in ante-natal care at the Royal Free Hospital from June 5th to 26th; in dermatology at the Hospital for Diseases of the Skin, from June 1st to 12th; in diseases of Children at the Children's Clinic and other hospitals, from June 15th to 27th; in tropical medicine, from June 15th to July 4th, at the Hospital for Tropical Diseases; and in medicine and surgery at the Prince of Wales's Hospital, June 1st to 13th. Courses of three months' duration in venereal diseases can be arranged, for women only, at the Royal Free Hospital; these courses will carry a special certificate; fee, 20 guineas. Copies of syllabuses for all courses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

The British Social Hygiene Council is organizing its sixth summer school, to be held at St. Hugh's College, Oxford, from July 29th to August 5th. The course is designed particularly to meet the needs of local authorities and national organizations at home and overseas who wish to secure for their officers, speakers, and health visitors instruction in the scientific foundations of social hygiene. The lecturers will include Sir J. Arthur Thomson, Professor Winifred Cullis, Dr. I. Feldman, Professor Cyril Burt, and Dr. William Brown. Particulars may be obtained from the honorary secretary of the Council, Carteret House, Carteret Street, S.W.1.

National Baby Week will be held this year from July 1st to 7th. A national conference on maternity and child welfare, organized by the National Association for the Prevention of Infant Mortality, is to take place in Cardiff on July 1st, 2nd, and 3rd, to discuss (*a*) an effective maternity service for the whole population; (*b*) the physical health of the normal child from 1 to 5 years of age; (*c*) the mental health of the normal child from 1 to 5 years of age; (*d*) children in institutions and boarded-out children. In connexion with the conference, lectures, a baby week film display, visits to child welfare institutions, and other activities, are being arranged in Cardiff. Further information regarding the conference may be obtained from the secretary, National Baby Week Council, 117, Piccadilly, London, W.1.

The International Labour Office has issued seven brochures, Nos. 243 to 249, dealing with the following subjects: solvents; tea and coffee, and telluretted hydrogen; tin; typefounders; ventilation; industrial hygiene, and workshops; and iodine. These publications, which form part of the general series, entitled *Occupation and Health*, are obtainable from the director of the London office of this organization, 12, Victoria Street, S.W.1.

The first issue of a two-monthly official journal for the American Society of Clinical Pathologists appeared in January with the title *American Journal of Clinical Pathology*, under the editorship of Dr. T. B. Magath. The January issue reproduces the presidential address of Dr. J. H. Black at the ninth annual convention of the society last year, and the clinical subjects dealt with include: the haematological aspects of agranulocytosis and other diseases accompanied by extreme leucopenia; agranulocytic syndromes; the Schilling count in appendicitis; the Kline precipitation test; the meningeal reaction to therapeutic serum injections; and a review of the present state of knowledge about cancer. The periodical can be obtained in England from Messrs. Baillière, Tindall and Cox, 8, Henrietta Street, W.C.2, the annual subscription being 23s. 6d., post free.

The Board of Education has published in pamphlet form a revised list of certified special schools for blind, deaf, defective, and epileptic children in England and Wales, and also institutions recognized by the Board as providing higher education for such children, together with a list of nursery schools. The institutions are grouped according to type and arranged in counties, details being given of the available accommodation in each. Copies of the list may be obtained from H.M. Stationery Office, price 9d.

Lady Chamberlain, G.B.E., wife of Sir Austen Chamberlain, K.G., has accepted the chairmanship of the British section of the Save the Children Fund, which is making a special effort to extend the provision of open-air schools for debilitated elementary school children, on the lines of the Fund's first open-air school at Broadstairs.

Major G. W. Dunkin, M.R.C.V.S., of the farm laboratories of the National Institute for Medical Research at Mill Hill, is on a visit, under the aegis of the Medical Research Council, to the United States, having as his primary object the study and discussion of the methods adopted in America for production of serums and vaccines in relation to animal disease, with particular reference to distemper. Major Dunkin bears with him a message from the National Veterinary Medical Association of Great Britain and Ireland to the American Veterinary Medical Association.

The King has approved of the appointment of Dr. Cyril B. Dear, acting chief medical and health officer, to be a nominated official member of the Legislative Council of St. Lucia, and of Dr. Stanley Branch, chief medical and health officer, to be a nominated official member of the Legislative Council of St. Vincent.

The following members of the medical profession were called to the Bar on April 29th: Dr. W. Calverley (Middle Temple), Dr. Mary J. Butcher and Dr. W. J. Butcher (Gray's Inn).

Before the war the Selborne Society started its extension work with a view to helping other societies to get good lectures, as distinct from courses, at moderate fees. It was found, too, that schools soon took advantage of the scheme in order to broaden their pupils' outlook, by giving them something not in the ordinary curriculum. The fourteenth annual edition of the society's lecture list can be obtained for 1s. from the assistant secretary, The Hermitage, Hanwell, W.7.

Circular letters 1202 and 1202A, issued by the Ministry of Health on May 8th, are in substance one circular, urging local authorities who are responsible for the housing of the working classes to increase and accelerate during the present building season the output of new houses and the repair of existing insanitary houses, a work which will not only improve housing conditions, but will help materially in alleviating unemployment in the building industry.

Dr. Cecil M. Rolston, chief medical officer, has been appointed an official member of the Legislative Council of the Presidency of Dominica.

A society of oto-rhino-laryngology for the Lyons district has been established, with Dr. Garel, the founder of laryngology at Lyons, as president for 1931.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to *The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Sour Milk

"H. R. M." asks whether the method advocated by Dr. C. A. Corban (May 2nd, p. 779) can be carried out in India, or will the temperature of that country affect the process? In what conditions is sour milk prescribed, and how does it differ from whey, or, as Indians call it, "chas"?

Foreign Ear, Nose, and Throat Clinics

Mr. W. S. THACKER NEVILLE (Harrogate) writes in reply to "Peroral": The best course of bronchoscopy is given in Paris in the summer by Chevalier Jackson. Another excellent course can be taken in Vienna, and Professor Portmann gives a six weeks' course in Bordeaux once a year.

Psoriasis

"A.M." writes: In reply to "A. D." I have never found the following fail to clear up psoriasis: half a drachm of solution of coal tar, 10 grains of ammoniated mercury, and soft paraffin to 1 ounce. The only disadvantage is that it stains the clothing. It can, however, be decolorized.

Cataract and Medical Practice

"SENEX" writes: I have a patient in active medical practice who is about to undergo an operation for cataract in one eye. He is anxious to know whether, supposing the operation is successful, he will be able to carry on medical practice as at present. The other eye shows some signs of commencing cataract, and may require operation later. At present the sight is very good. Also, supposing both eyes are operated on, would he be able to carry on medical practice with the aid of glasses? Of course, he understands that anyhow he will not be able to drive his car. Do you know of any case of a medical man carrying on under these conditions?

*** We have referred this query to Mr. Bishop Harman, who replies as follows: There is no reason why a medical practitioner who is in fair general health, and who has had a cataract removed from one or both eyes, should not continue to engage in medical practice. Vision after cataract operation is in the majority of cases good. There are certain difficulties that need to be overcome, but they are not insuperable. The chief difficulty arises from the necessarily high power lens required to give a satisfactory focus to the eye that has lost its crystalline lens. The higher the power of a lens the more is the area of good vision restricted. For the most part care is only needed when going down steps or stairs. But patients readily accustom themselves to the new conditions. If one eye only has been operated upon it is generally found that the patient prefers as his master eye the one that has not been dealt with, until such time as the lens opacities in this eye render its vision poor. I have just referred to my notes of three doctors who were operated on more than ten years ago. One had both cataracts removed; the other two had one cataract removed, the other eye being free from cataract. All three continued their work successfully, but, curiously enough, all were in special and not general practice. I may perhaps add that they were quite satisfactory patients, better than most laymen!

Left-handedness in a Child

"H. J. M." writes in reply to "M.D.": My daughter, aged 12, is left-handed, and I found that she made her own choice of side for all essential acts, and any attempt to coerce her caused great mental distress. Such children ought to be allowed freedom of choice, yet they should be encouraged to use the right hand for minor acts where the use of the left hand would be a handicap later on. I should certainly allow a left-hander to play games in the manner decided by a natural cause. I know no useful literature on the subject, despite a search, and I do not see how it could help. Applied common sense should decide the treatment, and the mother of "M.D.'s" patient might be influenced by pointing out the value of ambidexterity in the future, and the difficulty of deciding at the age of 3 years whether it is a case of real left-handedness or just a phase.

Piercing the Lobule

So many replies have been received in answer to the query by "Barbarian" in last week's issue (p. 829) that we have found it necessary to extract the main principles of each in the form of a brief general note.

The preparation of the skin may be done with surgical spirit or warm biniodide solution (1 in 6,000). In piercing the lobule two methods may be used. The first is one in which a fine trocar and cannula, or the smallest Southey's tube and trocar, are used, heat being employed as a sterilizing agent in each case. After withdrawal of the trocar a small gold ring called a "sleeper" is introduced through the cannula and left *in situ* after the cannula is withdrawn. The ring should be worn continuously for three or four weeks. "K.Y." jelly is a good lubricant in this procedure. It is essential to move the ring round and smear it every day with the antiseptic jelly, or ointment of yellow oxide of mercury. The second method is that of inserting a thread of silk or of silkworm-gut (prepared in 2 per cent. mercurochrome) with a fairly large, sharp, straight or curved surgical needle. In some cases a ring of thread can be formed, but by tying a double thread with knots close to the anterior and posterior openings a simpler "sleeper" is formed. The after-treatment consists in careful dressing under aseptic conditions, or by powdering with a preparation such as bismuth-formic-iodide. In the case of the circular silk "earrings," if the patient reports daily they can be turned slightly, so that a fresh piece goes inside the wound every day. It is advisable to mop the area with biniodide solution regularly. At the end of a week or ten days the silk can easily be cut away and the proper earring fitted. All our correspondents, by adopting the above methods, have had successful results, free from septic complications.

Dr. Christopher Woodhouse

Mr. L. WYNN HOUGHTON, F.R.C.S. (Berkhamsted) writes: With reference to the inquiry by "A. A. M." in the *Journal* of May 2nd for some facts concerning Christopher Woodhouse I append the information he requires. Extract from *The Parish Church of Berkhamsted St. Peter*, by R. A. Norris (1922, p. 68):

"Another regrettable loss is that of the stone from the grave of Christopher Woodhouse, who died in 1682, a loss due to the extensive works carried out in 1870. Woodhouse was a very prominent townsman, by profession a doctor of medicine; his name appears on the list of Burgesses, and he also served the office of *Bailiff*. Mr. Woodhouse lived in the house now known as the Homestead, nearly opposite the Alms Houses. Here he was visited by William Penn, who tried to induce Gulielma Woodhouse, Christopher's daughter, to go to his colony in Pennsylvania. Christopher Woodhouse was buried in the N. Transept. Chauncy describes the coat of arms on the tombstone, probably a floor slab, and gives the Latin inscription thereon in full. . . . Dr. Woodhouse appears to have had some reputation for curing 'bewitched persons.' See two singular pamphlets published by W. B. Gerish, Bishop's Stortford, 1921 and 1915."

Description of the coat of arms from Sir Henry Chauncy's *History of Hertfordshire* (1770): In a field sable a chevron argent, between three cinque foyles ermines, guttee de sangue with mantling, doubling, helmet, and for crest over a torse argent an Hercules issuant.

Income Tax

Professional Account: Balance Sheet

"B" explains that the whole of his professional receipts is paid into his bank, and cash is drawn to meet private and professional expenses. The latter are recorded in detail, and a chartered accountant prepares the annual statement of account from the bank pass-books and practice records. It is understood that a certified copy of this account is supplied to the inspector of taxes, but this official now requests to have a copy of a "balance sheet" also. Can this be required?

*** The strict legal position is that the inspector of taxes as such has no authority to require even an account of the receipts and expenses. He can, however, lodge an objection to the return, and the General Commissioners, by whom such an objection would be dealt with, have the right—and would presumably exercise it—of calling for such particulars as they may consider relevant. In general, the inspector of taxes requests to be supplied with such statements, etc., as he may consider the Commissioners would expect to be furnished, and in the case of businesses where substantial assets are involved, or where the nature of the receipts and expenses is such as to provide a wide margin for error and consequently require an additional check, balance sheets are usually called for and supplied. The balance sheet is, in fact, a normal part of the accounts which an accountant would regard as necessary for the information of a trader client. In the case of a professional practice, however, neither of the two conditions referred to above obtains, and, so far as our experience goes, a request that a medical practitioner shall supply a balance sheet setting out the assets and liabilities of his practice is very rare. Further, the balance sheet would be useless as any check upon the accuracy of the "cash" account, because it would have to include outstanding debts and changes which are not directly reflected in a single year's account prepared on the usual cash basis. That basis is possibly incorrect from the point of view of strict legality, but, unless the income is increasing or decreasing materially, or unless the practice is a "new" one—for example, in the years immediately following a change in proprietorship—it is almost always applied as a matter of concession in view of its obvious and great convenience. We therefore suggest that our correspondent should inform the inspector of taxes that as his request for a "balance sheet" is unusual in the case of a medical practice he does not see his way to incur the expense and trouble of having one prepared unless it can be explained to him why the case of his practice should receive exceptional treatment.

Appointment: Motor Expenses

"M.D.LOND." holds an appointment as M.O.H., and last year received £65 "towards his travelling expenses." In July, 1930, he sold his car for £50 and bought a superior car for £299. He is paying for the latter in instalments.

*** The cost of replacement is the amount which the replaced car cost him less £50. The excess of his expenditure over that sum represents improvement, and is therefore regarded as capital outlay. If the car is used for private as well as for professional purposes only a fraction of the replacement cost will be allowable, calculated according to the ratio of private to professional use. It is also possible that he will be required to satisfy the authorities that the allowance of £65 does not cover more than the running cost as a preliminary to receiving an allowance in respect of replacement.

Repairs to Premises

"C. R. H." inquires as to the admissibility of expenditure on repairs to the professional part of the premises. His accountant has pointed out that such expenses are already allowed for under Schedule A, in that tax is paid under that schedule on a net and not on a gross valuation.

*** It has to be remembered that in deducting a fraction of the Schedule A assessment as a quasi-rent paid for the professional portion of the premises it is the net value which is taken as a basis. Consequently in effect the practitioner simply pays on his profit, mainly under Schedule D, and to a small extent under Schedule A, and if no specific deduction is made for repairs none is received. But in any case the point is covered by Rules 3 (*c*) and (*d*) of Cases I and II, Schedule D. Rule 3 (*c*) provides for the deduction of the annual value or the part thereof used for purposes of the profession, and Rule 3 (*d*) for the deduction of sums expended for repairs of premises occupied for the purpose of the profession.

LETTERS, NOTES, ETC.

The Post-Influenzal Cough

Dr. G. A. GAREY SIMPSON (Lancaster Gate, W.) writes: I agree with Dr. W. A. Marris that the post-influenzal cough is due to a pharyngitis. I have invariably noticed that influenza, especially in the last epidemic, starts with a slight sore throat. I find collosol argentum, used undiluted with an all-glass atomizer, acts like a charm. The following will also stop the cough, especially if granules can be seen on the posterior wall of the oropharynx: Tr. krameriae, tr. myrrh, tr. cinchon., tr. kino, half an ounce of each. *Dose:* one teaspoonful to an ounce of water; use as a spray or gargle.

Metal Water-taps and Fittings

Dr. E. W. MATTHEWS (Medical Officer of Health, Kingston-upon-Thames) writes: With regard to the question raised by "Nest" (*May 2nd, p. 779*), I may say that chromium-plated water-taps were installed at my clinic about two years ago. The great difficulty is to prevent cleaners from using any form of metal polish, the result being that all the chromium was worn off within eighteen months. In a new clinic I have just opened I have solid stainless steel water-taps and fittings fixed, obtained from Adamsez, Ltd., 23, Old Queen Street, Westminster, S.W.1. They are very pleasing in appearance, and only need cleaning with a leather, and, I am informed, are not injured in any way by the use of metal polishes. *Needless to say,* they are rather more expensive, but I feel they are worth it.

Shantung School of Medicine

The Shantung Christian University School of Medicine was established in 1909 by the English Baptist Mission and the American Presbyterian Mission jointly, assistance being afforded by the China Medical Board of the Rockefeller Foundation. Despite national disturbances and interruptions of the work from time to time, progress has been continuous, and in the report for 1930 a favourable forecast of future developments is made. Beyond the routine education a certain amount of research is undertaken, and the department of pathology has been able to assist during the year twenty-three mission hospitals in seven different provinces. The teaching staff has more than doubled since 1918, and there is a gratifying increase in the number of students.

Medical Golf

There were close on 150 competitors for the Manchester and District Medical Golfers' Association's annual competition, which was held on May 6th at Wilmslow. The Challenge Cup, which was competed for by medal play over eighteen holes, resulted in a tie at 72 between Dr. J. Scott (Bolton), who was in receipt of 14 strokes, and Dr. C. E. Sykes (Withington), who had 18 strokes allowance. On the replay over nine holes, Dr. Scott was successful, with a net score of 37 against 42. Dr. Sykes won the captain's prize. There was also a tie for the Walter Gold Medal between Dr. J. N. Norman (7) (Pendleton) and Dr. J. L. Bradley (4) (Swinton), who each returned a gross score of 80. Dr. B. Robinson (Bowdon) won the Walter Silver Medal, which is awarded for the best gross score from a handicap of 10 or over.

Corrigendum

We are asked to say that by inadvertence the advertisement of the King Edward Memorial Hospital, Ealing, published last week, was incorrectly worded. The first vacancy announced should have been for an honorary assistant consulting *physician*, and not honorary assistant consulting surgeon as printed.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 56, 57, and 60 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 195.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

467 Acute Epidemic Serous Meningitis

H. SCHNEIDER (*Wien. klin. Woch.*, March 13th, 1931, p. 350) refers to several outbreaks of this disease in Germany, chiefly among children, during the summer and autumn of the last four years. The general constitutional symptoms are severe, but a lumbar puncture yields sterile fluid under increased pressure. The prognosis is favourable. The chief symptoms of this "aseptic meningitis" are its acute onset, with typical meningitic symptoms; the slightly turbid cerebro-spinal fluid, due to leucocytosis; the sterility of the fluid on direct examination and on culture; the relatively short course, rarity of complications, and the favourable prognosis; the absence of the ordinary causes of meningitis, such as otorrhoea, the exanthemata, and trauma; and the absence of epidemiological connexion with infective meningitis. Schneider has seen 24 cases since 1927; in 1928 twelve children were under treatment in Leipzig, and in 1930 thirteen children were attacked in Düsseldorf. The disease commenced with sore throat, headache and malaise, nausea and vomiting. Severe cases showed all the classical symptoms of meningitis; milder cases exhibited only a slight Kernig reaction: nuchal rigidity was not always present. One patient had headache and vomiting three weeks before admission; this was followed by the gradual onset of meningeal symptoms. In every case the blood pressure was normal, and no somatic changes were found. The tendon reflexes were brisk; oculomotor symptoms and papilloedema occurred occasionally. The cerebro-spinal fluid pressure was increased. The albumin reaction was positive, with an increased cell count which became normal during convalescence. The fever terminated by crisis or lysis, but in the severe relapsing cases the fever was intermittent. The prognosis is invariably favourable, according to Schneider; in one case ocular symptoms persisted, but complete recovery followed. The youngest of his patients was 14, and the oldest 72; the majority were healthy middle-aged adults; thirteen were females, and eleven were males. The Wassermann and tuberculin reactions were invariably negative. Animal experiments suggest that the so-called "serous meningitis" is an abortive form of epidemic meningitis.

468 Scarlet Fever in Sweden

A. LICHTENSTEIN (*Finska Läkaresällskapets Handlingar*, February, 1931, p. 89) records observations made at the Fever Hospital in Stockholm. Since the middle of last century, when thousands died every year from scarlet fever in Sweden, there has been a marked decline in its severity, the number of deaths from this disease in 1929 being only 91. The incidence of the disease has not, however, showed a corresponding decline. In 1920, for example, there were 9,750 cases and 190 deaths—a mortality of 2 per cent. In 1929 there were still as many as 8,579 cases and 91 deaths—a mortality of 1.1 per cent. During the last few years the ratio of relapses or recurrences has greatly increased, from an average of about 1 to 10 per cent. in 1929. This high recurrence rate may be connected with the present mildness of the disease, which effects a slower and less complete immunity than before. Haemolytic streptococci were found in 83 per cent. of about 3,000 patients on admission, and in 59 per cent. on discharge. The Dick tests carried out on about 2,700 persons of various ages yielded a curve corresponding exactly with that of the incidence of scarlatina at different ages in Stockholm. Of the 546 men in a regiment subjected to the Dick test during an epidemic of scarlatina in Stockholm, 40 per cent. gave a positive reaction; 24 of these positive reactors developed scarlatina during the following weeks, while not one of the negative reactors did so. The Dick test was repeated weekly in 575 cases of scarlatina, and was positive in just over 60 per cent. in the first week; some 10 per cent. continued to give a positive reaction. The serum of convalescents was given in more than 700 severe and moderately severe cases with good results. Antitoxic scarlatinal antistreptococcal serum has been given since 1925 in 600 to 700 severe and moderately severe cases in doses of 10 c.cm. or thereabout by intravenous injection. The results were excellent in uncomplicated cases, but this treatment seemed to have little effect on already existing complications.

469 Paratyphoid B Fever with Lung Complications

B. EDINGER (*Med. Klinik*, March 6th, 1931, p. 352) records two cases of paratyphoid B fever in men, aged 32 and 25 respectively, complicated by pleurisy with effusion. *B. paratyphosus* B was cultivated from the effusion as well as from the sputum in both cases. The disease ran a relatively mild course, and recovery ensued.

Surgery

470 Uraemia Following Blood Transfusion

Halter of Vienna has recently described a case of ruptured tubal pregnancy in which, after transfusion from a Group IV donor to the Group II patient, there was temporary improvement, but this was followed in twenty-four hours by icterus, oliguria and haemoglobinuria, and finally uraemia. P. WEISS (*Zentralbl. f. Chir.*, March 14th, 1931, p. 676) describes two further cases in which uraemia followed blood transfusion; in these cases, however, there was no haemolysis, and in one there was evidence of pre-existing nephritis. One was a Group II patient transfused from Group IV, and in the other case both donor and recipient belonged to Group III. Halter explained his case by assuming that the patient's corpuscles had been haemolysed by the serum of the donor, there being a severe anaemia to start with, and perhaps a strong agglutination titre in the donor's serum. Weiss considers that the evidence of haemolysis is insufficient; he thinks the explanation is that, as in his own cases, the kidney had been damaged by anaemia or infection, the excretion of protein from the donor's serum increasing the damage. In his opinion kidney disease contraindicates transfusion in such cases.

471 Urethral Syphilis

G. PINI (*Urol. and Cut. Rev.*, March, 1931, p. 182), who reports an illustrative case, states that numerous examples have been recorded of syphilitic lesions of the urethra. According to Casoli, chancre of the meatus occurs in 7 per cent. of all cases of syphilis. Endo-urethral chancres, even to the depth of 7 centimetres, have been described by Albarran, Ferrari, Jullien, Gebert, and Winternitz. On the other hand, cases of secondary papular syphilis of the urethra are very rare. This localization has been presumed in the older descriptions from the presence of a catarrhal discharge, from the urethra in syphilitic patients, which disappeared under specific treatment. But the demonstration of specific lesions in the urethral canal dates only from the use of the urethroscope and the discovery of the spirochaete in the urethral discharge. Late manifestations in the form of nodular, ulcerative, and gummatous lesions may involve the meatus, or, more rarely, the first part of the pendulous urethra, as reported by Johnston, Renault, Zeissl, and La Mensa. Pini's patient was a man, aged 24, who some months after contracting a characteristic primary lesion in the balano-preputial sulcus developed soreness in the urethra, pain on micturition and ejaculation, and slight urethral discharge. No gonococci were found, but on urethroscopic examination an eroded and tumid area indicating papular syphilis of the urethra was detected.

472 Injection Treatment of Inguinal Hernia

R. WOLFE (*Med. Journ. and Record*, March 4th, 1931, p. 243) discusses the injection treatment of reducible inguinal hernia from an experience of 22 cases. After skin preparation as for a major abdominal operation, and with the patient in a moderate Trendelenburg position, the hernia is completely reduced; 2 c.cm. of a 2 per cent. procaine solution is then injected into the canal, about half an inch below the internal ring, and lateral to the spermatic cord. With the needle still in position, 2 c.cm. of an alcoholic solution of catechu, krameria, monesia, *Vaccinium myrtillium*, *Rosa centifolia*, and *Rosa canina* are injected very slowly, taking from three to five minutes, and the needle is rapidly withdrawn. The patient is brought to a horizontal position and a truss is temporarily fitted over the area of the internal ring. Satisfactory results were obtained in 19 cases (86 per cent.). All the cases were ambulatory, and the hernias had existed from six months to fifteen years, with an age incidence of 21 to 81. The average number of injections was eight, the minimum being two and the maximum nineteen; no morbidity or mortality occurred in over 250 injections. The method should be restricted to cases of indirect inguinal hernia, and is contraindicated in cases of sliding or irreducible hernia. The author concludes that the procedure is worthy of further investigation, since satisfactory results have been obtained without any ill effects and without the necessity for treatment in hospital. It should be of special value in cases of poor surgical risk, old age, or refusal of radical cure by operation.

473 Radical Cure of Hallux Valgus

A. L. SORESI (*Surg., Gynecol. and Obstet.*, March, 1931, p. 776) describes a procedure by which hallux valgus, associated with a bunion, may be radically cured, even when the bursa has been infected; he resects the head of the metatarsal bone, and preserves the articular surface, thus reconstructing a normal phalango-metatarsal articulation. The head of the metatarsal is exposed, and the periosteum from the middle of the bone to about 1/4 inch from the articular surface is incised. The periosteum is separated around the bone, and the articular surface is detached. This can be done very easily if some bone is left attached to the articular surface itself; the spongy bone offers little resistance to a sharp instrument. The head of the metatarsal is then excised, sufficient bone being removed to straighten the toe. The excess of skin is removed with the bursa, and the wound is closed. A splint is applied, and the wound is covered by gauze impregnated with glycerin or alcohol. The toe is kept at rest until any inflammation has subsided; passive and active movements are then started. Soresi claims that the operation is anatomically and physiologically correct; that the results are functionally satisfactory is demonstrated by a case which he reports.

474 Renal Tuberculosis

R. GUTIÉRREZ (*Journ. d'Urol.*, February, 1931, p. 126) states that there are two different forms of renal tuberculosis, the medical and the surgical, but discusses the diagnosis and treatment of the latter only. He bases his conclusions on 65 nephrectomies, three of which are here recorded; they were performed at a New York hospital during the last ten years. At its commencement renal tuberculosis presents no well-marked anatomical lesion in the kidneys, but only a nephritis. The spread of the disease is at first almost always by the papillae, and dilatation of the calyces ensues by an ulcerative process which becomes ulcero-caseous or ulcero-cavernous. Simple nephrectomy will cure early cases; consequently early recognition is advisable, and in order to avoid diagnostic errors all exploratory measures (including cystoscopy and pyelography) should be employed. When the disease is advanced with involvement of the ureter, Gutiérrez advises uretero-nephrectomy, performed in two stages. The majority of post-operative complications are due to a septic ureteral stump left at a nephrectomy. Regional is preferred to general anaesthesia; the author uses 1 per cent. procaine. Patients should be given post-operative medical and hygienic treatment, and should lead strictly quiet lives, preferably in a sanatorium, for many years.

475 Arborescent Lipoma of the Tendon Sheaths

P. VALDONI (*Chir. d. Org. di Movimento*, February, 1931, p. 509) records a rare case of arborescent lipoma occurring in a lad, aged 19, who had suffered from pleurisy two years previously. In January, 1929, he presented a somewhat elastic swelling on the dorsum of the left hand and a similar smaller swelling on the right hand. In view of the history of pleurisy, a provisional diagnosis of tuberculosis was made. The swelling on the left hand was punctured, and some of the fluid was injected into a guinea-pig, but no tuberculous infection followed. Since the tumour did not disappear, it was excised; it was partly fatty, and with its many vessels almost resembled a naevoid condition. The right hand was operated upon in May; recurrence necessitated a second operation. Similar growths appeared in the sheaths of the peroneal tendons, but it was not considered advisable to remove them. At the first operation the swelling was solid and of a brownish-red colour; at the second it was cystic and arborescent. The recurrence was probably due to incomplete removal at the first operation. When the patient was seen seven months later he had complete functional use of both hands, and there was no sign of local recurrence. The condition of the feet had not become worse.

Therapeutics

476 Treatment of Spasmodic Croup

L. P. CRAWFORD (*New England Journ. Med.*, February 26th, 1931, p. 437) maintains that in the treatment of spasmodic croup the use of drugs and medicated vapours is erroneous and unsatisfactory, the spasm being, he thinks, a toxic manifestation of the absorption of colonic toxins from the small intestine. He found acetone in the urine of all patients with spasmodic croup, and also areas of dullness and tympany over the colon. The removal of impacted faeces which have caused gas to become collected in pockets in the colon relieves all the croup symptoms in a few minutes, because in this way the pressure of gas is taken away from the caecal side of the ileo-caecal valve, the strained valve having previously allowed the bacterial and faecal contents of the caecum to regurgitate into the small intestine, whence the absorption of toxins resulted. Three small soapy water enemas effect this usually; more than half a pint should not be given to a child, or more than a pint to an adult at any one time. The elevation of the syringe should not exceed twelve inches. As soon as the first enema has been expelled the second is given, and so in the case of the third. Neither laxatives nor large enemas should be administered, because the first forces and the second washes additional toxins into the small intestine in cases where the musculature of the colon is already incapacitated by the stretching due to pockets of gas. After appropriate treatment in this way the acetonuria vanishes, and the croup spasms do not recur on the subsequent days.

477 Soya Bean as a Milk Substitute

N. FOUND (*China Med. Journ.*, February, 1931, p. 144) discusses the food value of soya bean, which was not studied scientifically till 1900, though known in China since the time of Confucius. Experiments in infant feeding made by Ernest Tso in 1928 proved that soya bean flour, which has a protein content of 44 per cent., provides proteins easily digested by young infants, and is capable of producing continuous growth, but it is deficient in calcium, sodium, and chlorine, as well as in vitamins other than A and B. At the Evangelistic Centre, Seoul, large numbers of children have been satisfactorily fed on "soya bean milk" at a cost of less than one-third of that of condensed-milk feeding. The "milk" is prepared as follows. The beans are baked overnight in three times

their weight of water. The shells are removed in the morning, and the beans are ground in a mill, then boiled for five minutes, and filtered through a sieve. To every 1,000 grams of the filtrate there are added 20 grams of starch (previously made into a paste with some of the filtrate), 60 grams of sugar, 1.5 grams of calcium lactate, and 1 gram of common salt. This mixture contains protein 4.4 per cent., fat 1.8 per cent., and carbohydrate 1.5 per cent., with a *p*H of 6.8. The addition of cod-liver oil is essential.

478 Sugar in Therapeutics

H. PRIBRAM (*Forsch. und Fortschr.*, March 10th, 1931, p. 118) states that intravenous injection of grape sugar produces the following effects. (1) Strong solutions can remove water from the tissues, especially in cases of oedema. The success of this treatment is best seen in pulmonary oedema, where sugar may save life. The water withdrawn from the tissues is finally excreted by the kidneys. (2) This discharge of fluid from the tissues into the blood stream may also carry off metabolic waste products which have accumulated in the tissues. (3) As Pribram showed many years ago, sugar has an antidotal action, not only in the cases of poisons introduced from without, such as narcotics, veronal, salvarsan, and fungi, but also endogenous intoxication, such as uraemia. (4) Owing to the close relation between sugar and the liver, the combination of sugar with insulin therapy brings about good results in a number of diseases of that organ. (5) In other diseases also in which there is a reduction in the normal sugar content, especially as the result of excessive administration of insulin, sugar is beneficial. (6) It has a good effect on the heart and peripheral vascular system, so that it is useful in myocardial diseases and in many cases of high blood pressure. Sugar, therefore, whether administered by mouth, enema, or intravenous injection, may be of value in a number of different diseases, such as intoxications, infectious diseases, and disorders of the heart, kidneys, metabolism, lungs, and intestines; in the absence of diabetes its administration is absolutely harmless.

479 Dietetic Treatment of Obesity

In the last two years E. MOELLER (*Acta Med. Scand.*, February 18th, 1931, p. 341) has treated 46 patients suffering from obesity (excluding cases of diabetes, nephrosclerosis, myxoedema, exophthalmic goitre, and circulatory failure). Each received the same diet, yielding 950 calories: protein, 160; fat, 300; and carbohydrates, 490. Black coffee, broth, and 10½ oz. of vegetables were given daily, with 1¼ oz. protein. Water and salt were not restricted. Although the diet contains a fair amount of carbohydrate, the quantities of fat which must have been oxidized daily in many cases are so large that ketosis might have occurred, but only eight patients showed slight intermittent acetonuria. The ammonia output was always normal. Certain variations in weight reduction were attributable to the patients' departing temporarily from the prescribed dietary. The author argues that when normal or emaciated patients are underfed, the basal metabolism is reduced considerably. If this occurred in cases of obesity, it would be a strong argument in favour of thyroid treatment, but no significant change in the basal metabolism was observed. If the metabolism is reduced materially, there should be diminished weight reduction. When an ordinary patient with uncomplicated obesity received this diet an average weekly loss of 2⅜ lb. occurred, although in exceptional cases the reduction was 7 oz. only. Whenever the reduction was under 14 oz. there was reason to suspect infraction of the dietary. No undesirable results of prolonged under-nutrition were observed; a minority complained of hunger, but they admitted to feeling fitter on discharge than on admission. In three cases the reduction was between 31 and 25 lb.; in eleven cases, between 25 and 12½ lb.; and in twenty cases, between 12½ and 6½ lb. The average reduction for all patients was 10½ lb. Of 17 hyperpiesic patients, eight had a normal systolic pressure on discharge. The duration of treatment averaged 54 days.

Anaesthetics

480 Regional Anaesthesia

The employment of regional anaesthesia is strongly commended by V. E. WAN (*Nat. Med. Journ. of China*, December, 1930, p. 730), who records an analysis of 2,555 cases; of these 1,817 were field-block (with or without local infiltration), 85 were femoral, 361 sacral, 236 spinal, and 56 brachial block. There was almost invariable and complete success with field-block, femoral, and sacral anaesthesia. With spinal anaesthesia 90 per cent. of the cases were successful, while with brachial block 84 per cent. were considered satisfactory. There was no mortality, and the incidence of untoward sequels was so small that the author thinks that it constitutes no contraindication. Among the abdominal operations in which field-block was used, with or without local infiltration, were appendicectomy, exploratory coeliotomy, enterostomy, and drainage for generalized peritonitis or localized abscess. In thoracic surgery local infiltration was combined with intercostal nerve-block. In 81 per cent. of the spinal anaesthesia cases the success was considered perfect; in 9 per cent. it required supplementing with general anaesthesia; and in 10 per cent. it proved a complete failure.

481 Ethylene Gas Explosions

F. D. JOHNSTON and H. CABOT (*Arch. of Surg.*, February, 1931, p. 195) enumerate recommendations which they believe will provide a safe and workable system for the prevention of explosions during the use of ethylene-oxygen mixtures. Any electrical equipment or other apparatus producing heat must be absolutely prohibited in the vicinity of the anaesthetic mechanism. Static sparks outside the machine should be prevented by sheet metal flooring, in contact with cables to the ethylene-generating apparatus. The bare rubber rebreathing bag renders sparks possible, and if the introduction of a small quantity of a radio-active substance is not effective, a special manometric device is required; a diagram of a possible one is supplied. The exhaust gases must not be poured out into the operating room, and some device such as that suggested by Salzer must be installed. An electrical connexion betwen the patient and the metal operating table is essential. During the cold months of the year it is also advisable to make certain that the system is actually eliminating the danger from static electricity.

482 Amytal in Spinal Anaesthesia

H. KOSTER and L. P. KASMAN (*Med. Journ. and Record*, February 18th, 1931, p. 167) advocate the administration of amytal (sodium iso-amyl-ethyl-barbiturate) as an adjunct to spinal anaesthesia as being of value in eliminating the fear factor in apprehensive patients. The drug is supplied as crystals in sterile ampoules in 1 gram doses with an accompanying ampoule of 10 c.cm. of triply distilled sterile water for preparing a solution for intravenous injection. The patient having been told that it is necessary to obtain a drop of blood from a vein for examination, the solution is slowly injected at the rate of 1 c.cm. per minute. During its administration the patient falls into a sleep which is completely amnesic without any preceding nausea, laryngospasm, or excitement; the sleep becomes deeper as the injection continues. With large doses there is some cyanosis, and if the injection is made too rapidly a period of apnoea may occur. No preliminary narcotic or other preparation is necessary. After removal to the theatre, novocain is given intraspinally, and the operation can be performed in a moderate Trendelenburg posture with complete muscular relaxation and the elimination of physical and psychic shock. Under this anaesthesia 139 operations, most of them major, were performed, five being under amytal alone; no patient died. After the operation the patients usually slept for from six to twelve hours; there may be considerable restlessness, but less morphine is required post-operatively to keep them comfortable than is the case with those who receive spinal anaesthesia only.

Obstetrics and Gynaecology

483 Protein Therapy in Salpingitis

J. S. DIASIO (*Med. Journ. and Record*, March 18th, 1931, p. 291) reports his experience, in 101 patients, of the non-specific treatment of gonococcal salpingitis by intradermal injections of aolan, a bacteria- and toxin-free milk, in contradistinction to comparatively large doses intramuscularly. The procedure is based upon the observation that stimulation of the skin cells intensifies the autonomic changes in the internal organs that apparently produce the therapeutic effect. At one sitting 1 c.cm. is injected in three separate wheals, using 0.3 c.cm. of aolan for each. Daily injections are given, six constituting a course, which is followed by a rest period of several days; no injections should be given during menstruation and for two days after. In the majority of acute and subacute cases one course was sufficient, but chronic cases required two or more. Contraindications are syphilis, alcoholism, diabetes, myocardial insufficiency, liability to serum sickness, asthma, urticuria, epilepsy, and serious nervous conditions. All the author's patients became symptomless, and 43 were so markedly improved that they were considered cured after observation for ten months. Adjuvant local treatment consisted of application of 20 per cent. mercurochrome to the cervix uteri, vaginal insufflation of kaolin and sodium bicarbonate, hot douches, and as much recumbent rest as possible. Improvement in the condition was determined by vaginal examination in each case.

484 Pulmonary Complications of Pregnancy

F. H. PRATTEN (*Canadian Med. Assoc. Journ.*, March, 1931, p. 391) reviews the various pulmonary complications of pregnancy, with special reference to tuberculosis. He concludes that tuberculous women should be advised against marriage, unless the disease has been quiescent for two years, and that married tuberculous women should be given detailed instruction in suitable methods of preventing conception. Should they become pregnant, the induction of abortion during the early months of pregnancy is indicated and justified if the lesion is active, and particularly where there is laryngeal involvement. When pregnancy is permitted to continue, the most careful prophylactic measures are essential. Nursing the child should be invariably prohibited. The most unfavourable prognosis should always be given in cases showing marked constitutional symptoms which are out of proportion to the physical findings, and especially when there are laryngeal symptoms. Temporary improvement during gestation should not be rated too highly, since there is often a serious retrogression subsequently which ends in death. Pneumonia during pregnancy is considered by the author as the second most serious pulmonary complication, resulting as it does in deficient oxygenation both of the mother and of the foetus. Pneumonia causes interruption of pregnancy in 40 per cent. of cases in the first half, and of 60 per cent. in the second half. The maternal mortality is high. Pre-existing emphysema is aggravated by pregnancy; it may cause abortion owing to interference with the oxygenation of the foetal blood, or it may necessitate the induction of premature labour because of the serious condition of the mother.

485 Pregnancy and Tuberculous Laryngitis

P. LARREGLE (*Rev. Med. Latino-Americana*, January, 1931, p. 515), who records an illustrative case, states that tuberculous laryngitis is generally regarded as invariably fatal when it develops as a complication of pregnancy. His case, however, which occurred in a primipara aged 19, was exceptional. Treatment by absolute vocal rest, insolation of the larynx, injections of sanocrysin, and artificial pneumothorax enabled the patient to give birth to a healthy child at full term; two and a half months after delivery she completely recovered from her pulmonary and laryngeal lesions.

Pathology

486 Bovine Tubercle Bacilli as a Cause of Phthisis

B. LANGE (*Zeit. f. Hyg.*, March 18th, 1931, p. 298) records four cases of pulmonary tuberculosis in adults from which he was able to recover a tubercle bacillus of bovine type; in one case the bovine were mixed with human bacilli. Three of the patients had worked in close contact with cows, and it was this circumstance that led to the typing of the bacilli being carried out. Since there was no history of tuberculosis, nor of exposure to familial infection during childhood, the author considers that a primary infection had occurred in adult life. This view is to some extent supported by the fact that in one case, in which a careful post-mortem examination was made, no evidence of tuberculous lesions in the alimentary tract or its regional lymphatic glands could be found. Since tuberculous cows frequently cough up a large amount of infective material it is considered probable that the patients received a primary infection by the respiratory route with bovine bacilli. The disease due to the bovine type does not seem to be especially mild; two of the patients died with extensive pulmonary lesions. Altogether five cases of bovine infection of the lungs in adults have now been recorded in Germany.

487 Influence of Soap on Antiseptics

B. HAMPIL (*Amer. Journ. Hygiene*, March, 1931, p. 623) recalls his previous demonstration that certain highly germicidal phenol derivatives might be rendered inert by the addition of small quantities of soap; he now reports further investigations of a similar kind in connexion with mercurial antiseptics. He found that the antibacterial power of mercuric chloride against virulent staphylococci at 37° C. was remarkably increased by the addition of 1 per cent. or more of soap. Small amounts of soap gave irregular results, and larger amounts than 1 per cent. had no appreciably enhanced effects. The time of exposure required to bring about the result was five minutes, whether the organisms were exposed to the soap or to the mercurial solution first. The addition of soap to strong solutions of the germicide did not shorten the time for complete sterilization. Soap did not enhance the germicidal action against the members of the *coli*-typhoid groups, or against dysentery bacilli, *B. pyocyaneus*, and *M. catarrhalis*; indeed, in these cases it protected them for a short time against the mercurial salt. Mercuric bromide and nitrate were similarly strengthened in their germicidal action on *Staphylococcus aureus* by soap, but not on other organisms. If added to mercuric cyanide and *o*-chlor-mercuric phenol, soap increased the disinfectant action of these compounds three or four times, without any special selective effect for *Staphylococcus aureus*.

488 Acid Production by Brucella Strains

S. H. MCNUTT and P. PURWIN (*Journ. Infect. Dis.*, March, 1931, p. 292) have studied the production of acid in carbohydrate media by organisms of the Brucella group. In ordinary peptone water containing dextrose, levulose, galactose, xylose, or arabinose the medium becomes alkaline, even though chemical estimation shows that the sugars have been partly utilized. Apparently the acid produced by the disintegration of the sugar is more than neutralized by the alkali formed from the peptone. If the sugars are added to a nutrose medium, or, even better, to a nutrose medium containing 10 per cent. raw cow serum, a definite acidity is produced in the presence of arabinose, and a slighter but usually still definite acidity in the presence of xylose; with dextrose, levulose, and galactose the results are variable with the same strain from time to time. In media containing a sugar as the sole source of carbon, growth may occur in the presence of arabinose or xylose, but not in that of the other sugars. The acid production from arabinose and xylose is apparently of no value in differentiating the members of the Brucella group; forty-three strains from various sources were tested, but no satisfactory classification could be made by this method.

The Treatment of Rheumatism, Lumbago, Sciatica, Neuritis, Gout, etc. where due to excess of Uric Acid, by

AGOTAN (Howards)

Weintraud found that in gouty patients on a purine-free diet it **more than doubled the quantity of uric acid excreted in the urine.** Chase and Fine maintain that in normal and gouty individuals it induces an augmented excretion of uric acid in the urine and a decreased concentration in the blood by endowing the renal cells with **an increased power for eliminating uric acid.**

Some Medical Opinions:

M.B., Ch.B.:

"The gouty subject has a notoriously sensitive stomach and an impatient disposition. Many remedies for his condition which we know to be good have to be abandoned for one or other of these two reasons. Agotan, which is a recognised eliminant of uric acid, can be used in such cases in the form of an Ointment either alone or assisted by radiant heat. This ointment should be rubbed in not merely over the area actually affected in cases of 'rheumatism' or 'gout,' but for several inches all round so as to ensure absorption of a sufficiency of the drug. Both acute and chronic conditions of this kind are markedly benefited by it, and in Neuritis it is a veritable boon to all concerned."

M.B., B.Sc., D.P.H.:

reports that he has achieved success with Agotan when salicylates, iodides, ionisation and diathermy, etc., have all been, to use his own expression, "utterly futile." "With Agotan," he writes, "one can safely prophesy an ultimate cure. Even in cases where ultimate resort had had to be made to morphine this can be discontinued in a very short time. Progress towards recovery is never interrupted by exacerbations as is so common with the majority of other drugs."

M.D., C.M., D.P.H., etc.:

"I have run through the whole gamut of B.P. remedies, and I have tried, I think, all the proprietary uric acid solvents of the present day, but after many years of experience I have come to rely on AGOTAN as the most trustworthy preparation at present available. The conditions in which it may be prescribed with confidence embrace all forms of subacute rheumatism, muscular rheumatism or myalgia, including sciatica, brachial neuritis and gout, whether acute or chronic, and most of the gouty skin diseases. The last group often yields remarkably well to AGOTAN."

NOTE.—The ointment may be used alone or in conjunction with Howards' Agotan Tablets.

AGOTAN is the all-British make of Phenyl Cinchoninic Acid B.P.C. and is sold as powder in 1-oz. bottles and in 7½ grain tablets in bottles of 25 and 50 tablets, and in ointment form in collapsible tubes.

HOWARDS & SONS LTD. (Est. 1797), ILFORD, LONDON.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS

arranged for Doctors and Patients.

Medical Prescriptions made up to the minutest detail.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most *modern treatment of Mental and Nervous Disorders*. It *contains special departments for* hydrotherapy by various methods, including Turkish and Russian baths, *the prolonged immersion* bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas *situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied* to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, *Northampton*), *who can be seen in London by appointment.*

RATIONAL REPETITION IN THE TREATMENT OF RHEUMATISM
For many years Pistany has been appreciated by the Medical Profession for its great work in the cure of Rheumatism.
The properties of Pistany's hot volcanic soft mud are quite peculiar. Its power of stimulating and increasing the absorption of pathological products is still unrivalled.
The treatment may be continued by the patient after returning from the Spa, under his own doctor's supervision, by means of the Mud Packs, which are in use in many rheumatism clinics in this country.

BRITISH SPAS ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

The Chalybeate and Mud Bath in the Frankenwald, 1,906 ft. above sea-level. Proved in cases of anaemia, chlorosis, heart, nerve and women's diseases, gout, rheumatism, sciatica; bathing, drinking and air cures. Park, rest hall, forest environment. Information from the "Staatl. Badeverwaltung" and Travel Bureaux.

Exceptional curative successes. **Best installed Spas.**

ITALIAN HEALTH RESORTS

IN WINTER AND EARLY SPRING there are, in Italy, more SUNNY and WARM RESORTS and SPAS than in any other country in Europe. Many of them have the best all-round climatic conditions to be found in Europe.

IN SUMMER AND AUTUMN. The greater part of Italy is more pleasant in Summer than at any other Season of the year. There are HUNDREDS of DELIGHTFUL ALPINE, DOLOMITE, LAKE and SEA-SIDE RESORTS.

THE SPAS OF ITALY are world famous for their 'cures,' and besides those having seasons in the Spring, Summer, and Autumn there are many that have a pleasant Winter climate.

ENIT ALL THE YEAR ROUND ENIT

EVIAN-LES-BAINS

Safeguarding the Purchaser.

Although Advertising has become an integral part of modern business, its advantages to the consumer are not always clearly realised. A little thought will show, however, that any product marketed under a recognised name or trade mark must reach a high standard of quality, for were this not so "repeat sales" could not be secured; recognition of a discredited brand reacting to the disadvantage of the manufacturer in inverse proportion to the benefits that are derived when a large and satisfied clientele see, in the name of the product, a guarantee of quality and efficiency.

This argument leads one to expect that branded goods will represent better value than others, and that the standard will be maintained.

Advertising further benefits the purchaser by making possible reductions in the selling price consequent upon increased production resulting from the larger demand created by the advertising campaign. The manufacturer of advertised goods places his cards upon the table, supplying information concerning the product which enables the prospective purchaser to form a judgment upon its suitability to his own particular needs, whereas non-advertised goods rely entirely upon recommendations, often of a confused nature, and it is left to the purchaser to find at his own cost the real value of the product.

It is safe, therefore, to assume that in the majority of cases advertised goods only should be purchased. The advertisement pages of the *Journal* contain offers of a variety of goods and of service designed to meet the professional and personal needs of the medical man.

It should be remembered that while the acceptance of advertisements for publication in the *Journal* is not to be understood to imply a recommendation or guarantee, and while no responsibility can be accepted with regard to the accuracy of the statements contained in advertisements, a very strict censorship is maintained by the Journal Committee, and every effort is made to ensure that the claims set forth are well founded. In this way a degree of confidence has been established between readers and advertisers in the *British Medical Journal* which cannot be paralleled by any other similar publication in the British Empire.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London.

Oxford Street, W.1.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants. Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, SOUTH-WEST.—Very sound good middle-class PRACTICE, old-established, and held by the Vendor for twelve years. Average gross cash receipts nearly £1,600, including panel of over 1,700. Fees 2/6 to 10/6. Very little midwifery. Good-sized house, with 2 reception, 6 bedrooms, etc. Price £1,000. Premium £2,365.
2. PARTNERSHIP.—YORKSHIRE.—LARGE CITY.—A one-third share, with succession to the whole Practice in about one year's time, is offered in a rapidly increasing PRACTICE, producing for the last 12 months approximately £2,300, including panel of 1,500. One appt. worth £150. A suitable house will be vacant shortly. Premium £1,200. Large scope for further development.
3. LONDON, N.W. (Kentish Town area).—In a well-populated district a mainly working-class PRACTICE, producing for twelve months ending March last £728, including panel of 260. House contains 10 rooms, with small garden; garage. Rent £120 p.a. on lease. Premium £1,000.
4. PARTNERSHIP.—COUNTRY TOWN.—Within 130 miles North of London—A fifth share, representing about £1,500 p.a., is offered in a particularly sound good mixed-class Practice, having substantial panel. Fees from 4/-. Not much midwifery. Suitable accommodation available. Premium 2 years' purchase. Ingoing partner should be a keen worker, and preferably Scotch or English.
5. LONDON (WEST END).—Old-established non-dispensing and non-panel PRACTICE, averaging over £4,700 p.a. Visits (very few) and consultations from one guinea upwards. No midwifery. Suitable accommodation available on rental. Premium £6,000. Good introduction given. Personal application desired.
6. NORTHERN CATHEDRAL CITY. — Old-established good mixed-class PRACTICE, averaging over £1,100 p.a., including panel of 1,070. Fees from 3/6. Not much midwifery from 2 to 10 gns. Very suitable small house, with 1 sitting, 3 bedrooms, etc. Garden. Garage. Rent on lease £50 p.a. Good sport and first-class schools. Hospital, and prospect of appointment on staff. Premium for prompt sale £1,550 cash.
7. LANCS.—LARGE TOWN.—PARTNERSHIP.—A one-third or two-fifths share is for disposal in well-established and increasing middle and working-class Practice. Gross cash receipts for immediate past 12 months £3,150. Panel of over 3,000. Appts. worth about £80 p.a. Fees from 2/6. Choice of two houses, both at moderate rentals. Premium only 1½ years' purchase.
8. WITHIN 20 MILES OF LONDON (WEST).—Rapidly developing district.—PARTNERSHIP.—A half share in a well-established good middle-class Practice, averaging over £3,500 p.a. Panel of 1,100 and appts worth £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.
9. SURREY.—COUNTRY PRACTICE.—Very old-established, and situated in delightful district. Gross cash receipts for past 12 months £2,000, including panel of about 700. Fees from 2/6 to 21/-. Midwifery 3 to 20 gns. Exceptionally nice house, with 2 reception, 6 bedrooms, and professional rooms. Nearly 2 acres of garden. Price, freehold, £3,000. £1,800 on mortgage. Premium £3,000.
10. CHESHIRE.—NEAR COAST.—Old-established good mixed-class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,280. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. Rent on lease £85 p.a. Premium £2,300.
11. PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase later, of an old-established mixed-class Practice offering good scope. Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium 2 years' purchase. Ingoing partner should be about 30, English or Scotch, and pref. married.
12. WITHIN 30 MILES OF LONDON.—In a delightful residential district (well populated and growing rapidly), a small PRACTICE, producing last year £406, including panel of 300, and capable of considerable development. Very good residence (suitable for resident patients) in about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400 Excellent schools, good society, and sport.
13. FAVOURITE COAST TOWN —Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 3/6 to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. large garden. Freehold for sale. Premium £3,000.
14. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.
15. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.
16. PARTNERSHIP.—SOUTH-WEST LONDON.—A one-third share is for disposal in very well-established chiefly middle-class Practice, producing last year about £5,500, including panel (rapidly increasing) of 1,600. Fees from 2/6. Suitable house can be rented on lease. Premium 2 years' purchase.
17. PARTNERS[illegible] within 80 miles of London.—A [illegible] for disposal owing to the retirem[illegible] in an exceptionally sound mixe[illegible] receipts £3,500 p.a., including panel of 1,000. Fees 2/6 to 25/-, medicine extra. Premium only 1½ years' purchase for quick sale, owing ill health.
18. LONDON, WEST [illegible] gly mixed-class PRACTICE, [illegible] £1,790, including panel o[illegible] House in excellent repair, [illegible] room, etc. Price for freehold £2,500. Premium 2 years' purchase.
19. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast; producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. *Premium* £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy [illegible]port.
20. [illegible] one-third share is offered in [illegible]g over £1,700 p.a., including panel of 470 and appts. of about £100 p.a. Fees 3/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. Premium 2 years' purchase.
21. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
22. SOUTH CORNWALL.— [illegible] PRACTICE producing about £700 p.a. [illegible]600. Fees 5/- to 21/-. Suitable house, [illegible]ms, etc. Rent on lease £50 p.a. Good sp[illegible]ium only 1 year's purchase. Ill-health reason of sale.

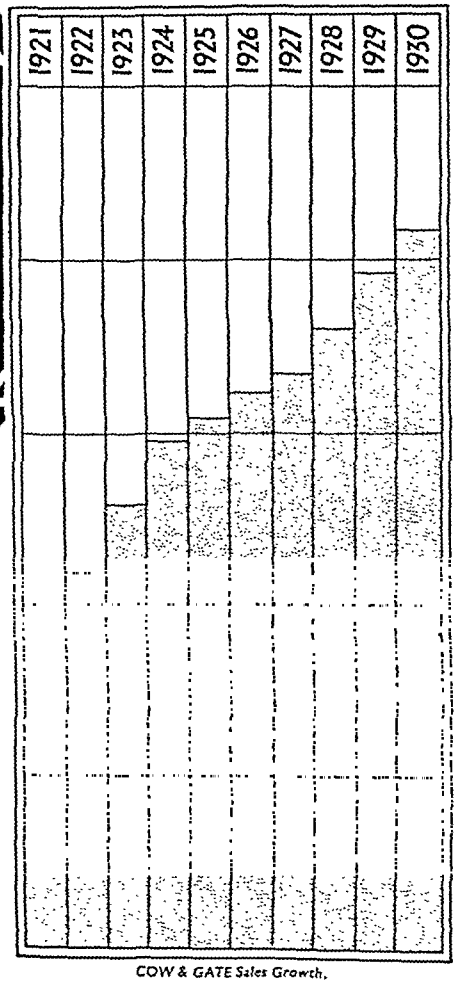
Facts WHICH SPEAK for THEMSELVES!



COW & GATE Sales Growth.

COW & GATE Milk Food is now supplied to almost every Hospital and Welfare Centre in this country, although it is the highest priced food on the market.

We illustrate here a graph showing the COW & GATE sales growth during the last ten years.

THERE MUST BE A REASON FOR THIS EXTRAORDINARY GROWTH!

It is because the Medical Profession has over a long period proved the value of COW & GATE, and insist on having the best!!

Support Home Agriculture. COW & GATE LIMITED is an all English Firm, using only home produced milk.

Write for particulars of our special Milk Foods for difficult Infant Cases.

"The best milk for babies, when natural feeding fails"

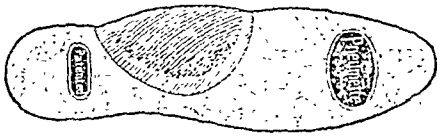
"FLAT FOOT"

or a "Falling of the Arch"

Is the cause of many true and false ailments. There are aching, swollen or painful feet, walking is a trouble, one soon gets tired, ankles are weak and liable to "turn over," cramp at times in the toes, feet, or legs, weakness at the knees; there are pains similar to rheumatism or sciatica—all traceable to the condition of the feet.

THE "PNEUMETTE" IS THE REMEDY.

(Patented and British.)



THE ONLY FOOT ARCH SUPPORT WITH AN AIR CUSHION. YOU WALK ON AIR—not on metal. You don't feel them—only the wonderful support they give.

The Effect in most cases is Immediate.

What the Pneumatic Tyre is to the car **"Pneumettes"** are to the feet.

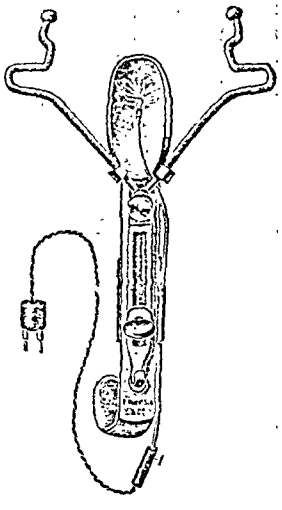
MODEL A.—For Flat Foot or Trouble under Instep. Price per pair 16s. 6d.

MODEL B.—Combined Support for Main and Metatarsal Arches. Price per pair, 17s. 6d.

PAMPHLET ON FOOT TROUBLES, with an Article, "The Medical Aspects of Flat Foot," by an eminent London Physician, free.

SOMETHING NEW.

Dr. Guttman's (German) SELF-HOLDING VAGINAL SPECULUM, Chromium plated.



Complete with Davidson's electric attachment, rheostat, spare lamp, and "Davon" Battery, in case

£5 5 0

Note.—The "Davon" Battery has a well-earned reputation in the medical world for reliability and long life. Our guarantee is behind it.

EXAMINATION CYSTOSCOPE.

(Foreign)

"Kollmorgen" optical system.

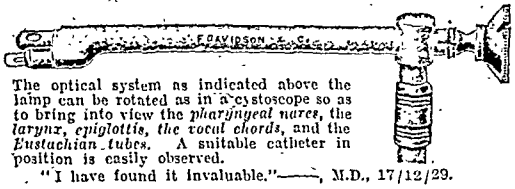
Giving a very brilliant upright image.

Complete in case, with spare lamp, £5 17 6 while stock lasts (usual price £9 9 0).

ELECTRIC PHARYNGOSCOPE

(Foreign)

(New optical system giving much improved view.)

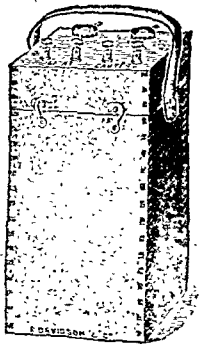


The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx, epiglottis, the vocal chords*, and the *Eustachian tubes*. A suitable catheter in position is easily observed.

"I have found it invaluable."——, M.D., 17/12/29.

Pharyngoscope, "Davon" Battery, and Rheostat in Walnut Box	7 5 6
Pharyngoscope alone or with Battery (not the "Davon") in handle	5 15 0
"Davon" Battery 7/6. Walnut Case	10 0
Ear, Nose, and Throat Outfits from	3 12 6

"DAVON" PORTABLE SET FOR CAUTERY & LIGHT.



No. 18C. 0 to 4 Volts.
Actual capacity 20 ampere hours.

This constitutes an achievement in the production of a highly efficient apparatus at a moderate cost.

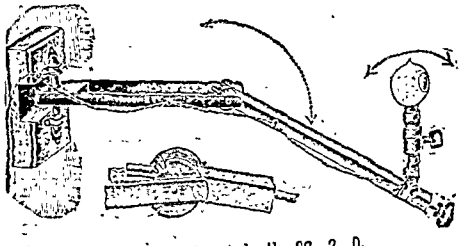
No. 18C comprises a new pattern 4 volt glass accumulator made without plate separators and concealed rheostats for cautery and light actuated by rotating knobs on the lid. These permit of very easy and gradual adjustment. Separate terminals for cautery and light allow of both being employed at the same time.

In Walnut Box with strap handle Price ... ... £4 4 0.

Cautery Handle, Cords, and 2 Burners ... £2 4 6.

THE "DAVON" BRACKET.

Well made and serviceable at a very MODERATE PRICE.



Price without bulb £2 2 0.

Target frosted bulbs (please state voltage) each 3/6.

OCULIST'S TRIAL CASES.

In large variety from £10 10 0 complete.

All lenses mounted, and adjustable trial frame.

Secondhand cases frequently in stock at tempting prices.

TEST TYPES, &c., of every description.

EMPLETS

Enteric-Coated Gland Products

AN improved form for the administration of gland products is furnished by the "Emplet" series of compressed tablets coated with a special acid-resisting material.

This enteric coating is the result of many years of research work in the Parke, Davis and Co. Laboratories. It contains no salol and is therapeutically inert.

Gland substances enclosed in this material are protected from possible inactivation through destruction of the active principle by the hydrochloric acid and pepsin of the gastric juice. As the Emplets readily disintegrate on contact with the alkaline secretions of the duodenum, the gland substances are released at the zone of maximum absorption.

Clinical evidence suggests that gland substances administered orally in Emplet form are more effective than when given in ordinary uncoated tablets.

The following gland substances are supplied in EMPLET form:—

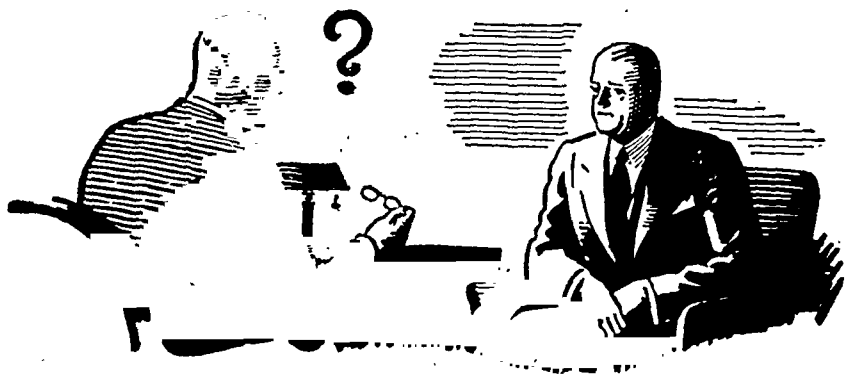
Corpora Lutea 2 gr.
Orchic Substance 5 gr.
Ovarian Substance 5 gr.
Ovarian Residue 5 gr.
Parathyroid 1/10 gr.
Pituitary (Whole) 1 gr.
Pituitary (Anterior) 2½ gr.
Suprarenal 2 gr.
Thyroid, gr. ½, 1¼, 2½ and 5 grs. (fresh)
Thyroid-Ovarian

FURTHER PARTICULARS WILL BE SENT ON REQUEST.

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1.

Laboratories: Hounslow, Middlesex. .·. *Inc. U.S.A., Liability Ltd.*

D



The Answer to the "first Question"

INVARIABLY before prescribing for any ailment, the first question the physician asks the patient concerns the function of the bowels.

He then naturally asks himself what corrective, if any, to prescribe to suit the condition, without interfering with the treatment.

Agarol provides a safe answer to this.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is free from any artificial flavouring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, *gentle stimulation* of peristalsis, makes the result certain and the re-establishment of regular habits possible.

One tablespoonful at bedtime —is the adult dose.

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

Announcement of the British Medical Association

British Medical Journal

Special Number June 6th

EVERY special issue of the British Medical Journal may be expected to provide material of interest to a large proportion of the profession. The next Special Number, to be published on June 6th, will include among its principal contents two recent lectures of much importance, one of them being accompanied by coloured illustrations on art paper plates. Original articles and clinical memoranda, covering a wide field of practice, will also be published together with full information about the Annual Meeting of the British Medical Association to be held at Eastbourne in July.

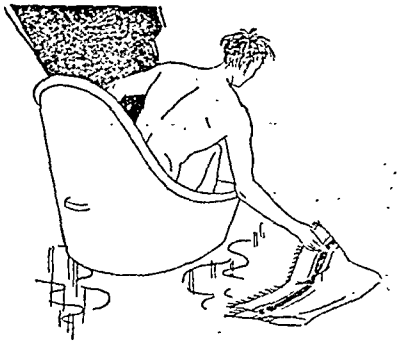
Mention may be made here of the carefully compiled advertisement sections in the Special Number. Readers have, at all times, shown their appreciation of advertisements appearing in these columns, and it is well known that their practical support has contributed to the high regard in which the British Medical Journal is held throughout the Advertising world. The advertisements published week by week constitute, in effect, an exhibition of current medical and surgical requisites which the doctor mindful of his obligations cannot fail to examine, for this is the recognized channel through which information about the accessories to practice may be obtained.

The forthcoming Special Number replaces the usual issue due to appear on the same date, and it will be sent to all members of the British Medical Association in the customary way. Despite the higher cost of production, due to reproductions in colour, there will be no increase in the normal charge of 1s. 3d. per copy made in respect of copies purchased by non-members.

Enquiries concerning the Journal should be addressed to:—

The Manager, British Medical Journal,
B.M.A. House, Tavistock Square, London, W.C.1

The man who had your practice 100 years ago . . .



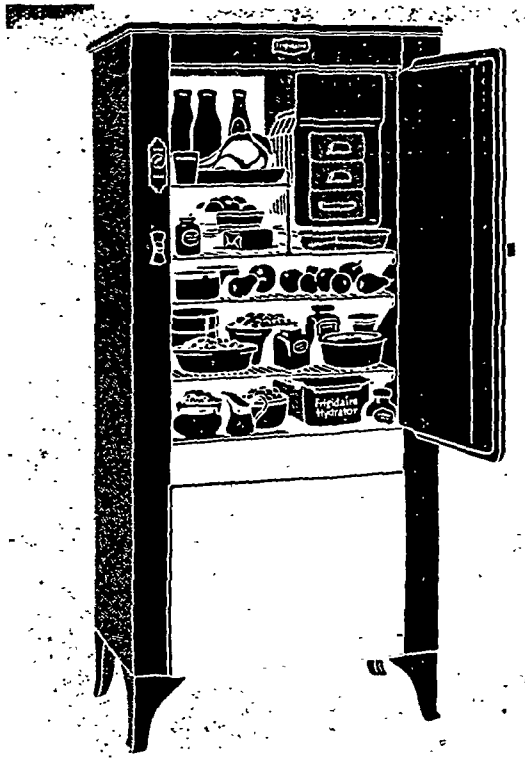
probably bathed in a tin tub and got about on a cob. You enjoy "h. & c." and a motor car. That's Progress . . . . the sloughing off of old ideas . . . . Hundreds of doctors to-day are already discarding old-fashioned ideas about keeping food. Knowing the importance of "controlled temperature" for *pure* food, they have installed Frigidaire. Their food tastes better, because it is always fresh. They have ice in plenty for hot weather needs. Their wives have no worries about food preservation nor food wastage . . . . Send the coupon and find out how inexpensively you may enjoy these benefits.

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric Refrigerator. Here are just a few of them.

The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

The automatic feature of Frigidaire is invaluable. The safety of your food does not depend on a maid's vigilance. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.



Practical, flat top, makes a useful shelf.

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc., etc. Even *wilted vegetables will* regain their crispness here in a few hours.

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

Frigidaire Cabinets are all white porcelain on steel—the finest durable finish it is possible to have. And easily kept clean by just a rub with a damp cloth.

The new Frigidaire is quiet—you *can't* hear it start, stop or run.

SHOWROOMS AT 141, NEW BOND STREET, LONDON, W.1, AND IN ALL PRINCIPAL TOWNS.

COUPON

FRIGIDAIRE LIMITED (*Incorporated in Canada*)

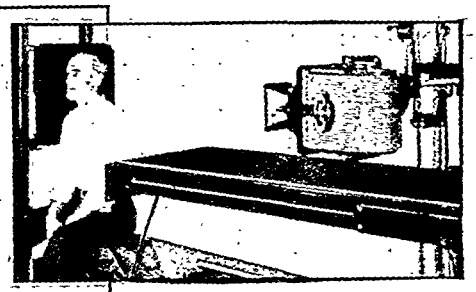
THE PROFESSION RENDERS ITS VERDICT ON THE VICTOR SHOCK PROOF



These photos of a Model "B" Shock Proof X-Ray Unit show how one Coolidge tube serves for all positions in radiography and fluoroscopy, both under and over the table. The same flexibility is realized with the table in vertical and angular positions.

"Never Before Such Satisfaction"

"I have used a wide variety of equipment in my twenty years of application to this work," writes the head of an X-ray Laboratory, "and have never experienced before such satisfaction and pleasure in handling any apparatus as this. To one who admires fine workmanship, excellence of design and ease of operation, the Shock Proof is ideal."

Another Physician writes, "I cannot praise the Victor Shock Proof enough. As a piece of mechanical construction, it is a delight. Quick and responsive to every change in position, anyone can operate it . . . to one situated as I am this outfit is well-nigh perfect. Uniformity in radiographic results is certain, together with remarkable clarity and beautiful contrast. One can undertake with assurance lateral spine and all abdominal work, and can do fine chest work with flash exposure. The unit is shock-proof and with reasonable care should last a life-time."

Not only in the doctor's surgery, but also in Mental or Nervous Institutions and Children's Hospitals, does the Shock-Proof fit in better than any available equipment. Its unique 100% electrical safety is the reason.

A full appreciation of the Victor Shock Proof and its significance may be gained through reading an illustrated brochure we have prepared. Won't you write for a copy to-day?

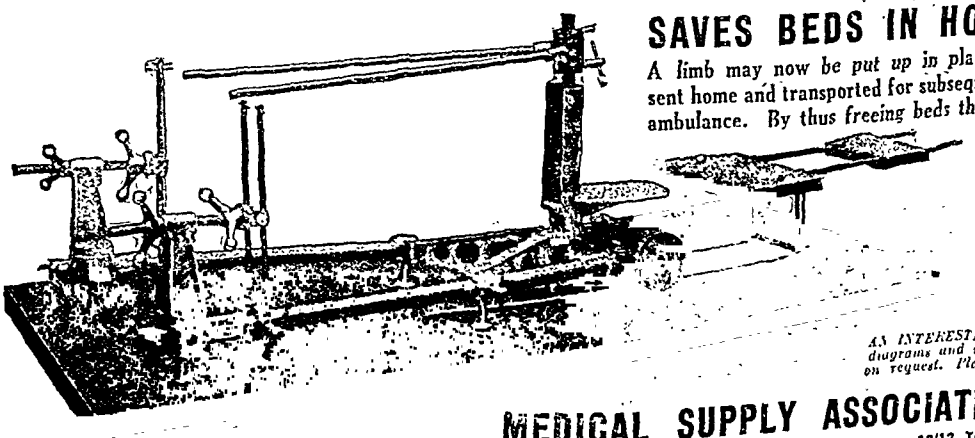
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk: also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in. × 15in. × 11in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

THE MODIFICATION OF COW'S MILK

BY **ROBINSON'S**

"patent" **BARLEY**

What milk can do depends on whether milk can be thoroughly and easily digested. Fresh cow's milk if taken with Robinson's "Patent" Barley is practically as digestible as mother's milk. Taken alone it forms a clot in the stomach—and in infants this must, of course, be avoided.

The accompanying photographs illustrate an experiment carried out in the Research Laboratories of Keen, Robinson & Co. Ltd. These show in a graphic way how Robinson's "Patent" Barley prevents the formation of the tough indigestible clot.

Physicians are invited to send for Clinical Reports from Hospitals and General Practitioners in all parts of the world.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

JB 94

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

ALKA-ZANE

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.

The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A supply for clinical use and literature sent gratis to physicians on request.

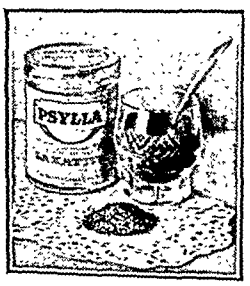
TWO NEW PREPARATIONS

Vide THE LANCET, Jan. 10th, 1931.



"PSYLLA (psyllium seed); LACTO-DEXTRIN (Battle Creek Food Company, Mich., U.S.A., Distributing Agents, Coates & Cooper, Ltd., 41, Great Tower Street, London).—This company have sent us specimens of their laxative agent, Psylla, and their preparation, Lacto-Dextrin, for use in intestinal toxaemia. Psyllium seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in Fissure or Haemorrhoids. The same firm has received favourable reports from the clinical use of their combination of lactose and dextrin."—*Lancet*, Jan. 10th, 1931.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, Ltd., 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

INSULIN (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.

It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

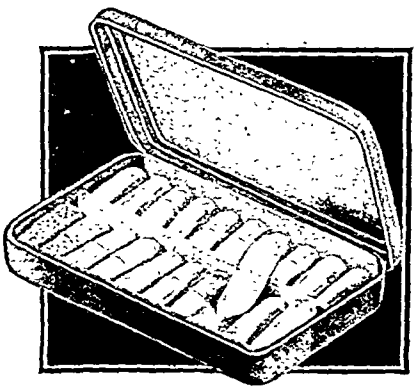
A *New* chemo-therapeutical preparation

for the treatment of influenza, septic diseases and toxemias



Used in America for treating Influenza for the past two or three years with great success. The physician's sample illustrated here will be sent to you free on request.

Indications.
Influenza Colds, Pyelitis, Puerperal Sepsis, Surgical Sepsis, Bronchial Asthma, Obstetric Morbidity, Cystitis, etc.

DISULPHAMIN is a mixture of Sulpho-salicyl formol sodium nucleinate and Dimethylamino-antipyrin combined with camphor. The antitoxic action is based on the assumption that Disulphamin transforms the toxic colloid to a crystalloid, thereby facilitating its dialysis through the walls of the blood vessels, and accelerating its elimination by the kidneys.

While phenol is bactericidal in a 1/100 dilution, Disulphamin is bactericidal in a dilution of 1/10,000 to 1/50,000.

In a series of tests made in the treatment of Influenza with Disulphamin, it was found that the course of the disease was materially shortened, and very seldom did Broncho-pneumonia or other complications supervene. Although the etiology of influenza has not yet been clearly determined, it appears that Disulphamin exerts a polyvalent action.

The clinical results thus far obtained are so encouraging that physicians have ample justification for employing Disulphamin in Febrile Toxemias arising from Sepsis.

Samples and literature, including charts of actual tests and important hospital findings, will be sent free on request to Messrs. COATES & COOPER, Ltd., 41, Great Tower Street, London, E.C.3.

TRADE "HEPATAGEN" MARK

(MIST. HEPATICA CONC. HEWLETT).

COMPOSITION—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general aperient and cholagogue, has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed only in 5-oz., 10-oz., 22-oz., 48-oz., and 90-oz. Bottles.
Price in England, 12/6 per lb.

This preparation is also supplied "*sine* Cocaina," the dose and price remaining the same.

The Medical Profession
when prescribing
"Liquor Carbonis Detergens"
SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's *Liquor Carbonis* Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Kaylene

for the treatment of acute intestinal infections, ptomaine and other forms of food poisoning, and all diarrhoeal conditions. It acts by adsorption and is the true antidote to bacterial toxins and toxalbumins in contaminated food.

The action is speedy and certain.

Kaylene-ol

An emulsoid of the toxin adsorbent Kaylene combined with a highly viscous Liquid Paraffin. The latter counteracts the consolidating effect of the Kaylene. This preparation may be prescribed with confidence for those conditions in which toxaemia is associated with constipation. It actively prevents the absorption of toxins and completely puts an end to the fouling of the lymphatics and the blood.

Samples and "adsorption" literature obtainable on request to the Manufacturers:

AETHER PURISS. B.D.H.

The crucial test of an anaesthetic is its every-day use in the widely-different conditions associated with hospital and private practice.

The Crucial Test

Anaesthetists and surgeons alike have come to depend on Aether Puriss. B.D.H. for the production of a deep, comfortable and safe anaesthesia—as the following reports, typical of many, indicate:—

Every-day Routine

"... nothing but praise for Aether Puriss. B.D.H. ... just used it for two gynaecological anaesthetics, its smoothness of action gives one every confidence in administration. ..."

Hospital

"... Aether Puriss. B.D.H. excellent in every respect. I use it exclusively in my private practice. ..."

Private Practice

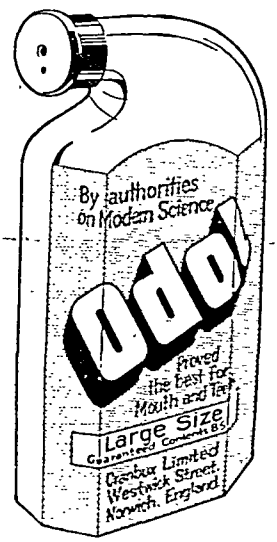
The Gargle and the Child

Whilst medicine, though unpleasant to take, can be forced on the unwilling child, it is not so simple a matter to compel a child to gargle. The act of gargling cannot be enforced, and, where the actual gargle is disagreeable, few children will submit. Therefore, a very necessary act is often scamped or entirely avoided.

Odol Mouthwash very successfully solves this problem. Its very pleasant taste appeals to the child and its proven bactericide efficiency achieves the desired results. Moreover, Odol is absolutely harmless and cannot injure the delicate mucous membrane of the child's mouth.



Samples and literature will be gladly sent to members of the Medical Profession on request.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

Works: KING'S LANGLEY, HERTFORDSHIRE.

M233

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

Alasil

M 279

BACILLUS COLI BACILLURIA & URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B. coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

STANIFORM
Regd.

BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contraindicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Kliniek (Utiecht, Holland), in cases of bed sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

MILK POWDER for SAFETY!

The following extracts from *The Lancet*, and the Presidential Address at the Royal Sanitary Institute Congress at Margate, show the risk run in feeding raw milk to infants:

'There can therefore be no doubt that a fair proportion of cases of ordinary adult phthisis in Scotland are due to the bovine bacillus .....'—*The Lancet*

Extract from the Annual Report for 1928 of the Medical Officer of Health for———

INFANTILE DIARRHŒA

"Until the methods of farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, *I am definitely of the opinion that liquid milk should be banished from the dietary of infants.*"

.... 'But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years of age is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended.'

Extract from Presidential Address, Royal Sanitary Institute Congress, Margate.

Cow & Gate Milk Food

"The best milk for babies, when natural feeding fails."

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

AROCAN

The word AROCAN indicates a series of local anaesthetics specially prepared at Evans' Biological Institute, containing a highly purified form of diethylaminoethyl-p-aminobenzoate, hydrochloride, and Adrenalin in various strengths.

AROCAN Solutions are remarkably stable, keeping satisfactorily for an indefinite period; can be boiled without loss of activity, and are in themselves sufficiently antiseptic to inhibit the growth of any contaminating organism.

AROCAN Solutions are not subject to the Dangerous Drug Act Regulations, containing no cocaine, and are relatively non-toxic. Three strengths are issued as follows:—

AROCAN LOCAL ANAESTHETIC is a solution containing 2% diethylaminoethyl-p-aminobenzoate, hydrochloride, and Adrenalin 1 in 50,000. It is specially prepared for REGIONAL ANAESTHESIA and, diluted, is suitable for MINOR SURGICAL OPERATIONS.

AROCAN DENTAL ANAESTHETIC contains 2% diethylaminoethyl-p-aminobenzoate, hydrochloride, and Adrenalin 1 in 10,000.

AROCAN SPINAL ANAESTHETIC contains 5% diethylaminoethyl-p-aminobenzoate, hydrochloride (known as Novocaine, Procaine, or Ethocaine B.P.C.), and Adrenalin 1 in 25,000.

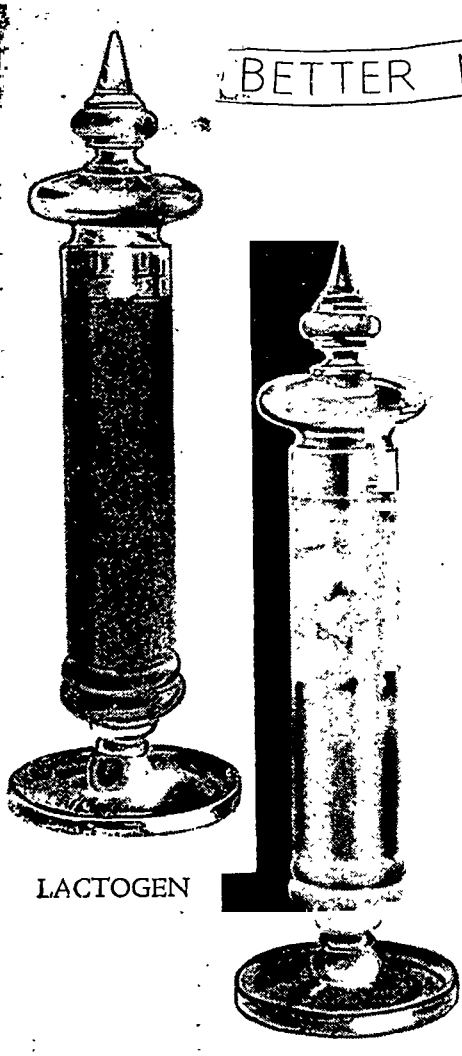
BETTER MILK FOR BABIES



LACTOGEN

COWS' MILK

FACTS ABOUT
LACTOGEN

Digestibility

*(2) The Protein Content

The digestibility of any milk diet is to a large extent governed by the nature of the curds formed during digestion. The large firm curds of unmodified cows' milk are in marked contrast to those of breast milk, which, being fine and flaky, are easily digested. In the preparation of Lactogen the protein undergoes an essential modification, and the curd formed during digestion is of a finely flocculent nature so characteristic of the natural diet. Lactogen provides a protein allowance comparable with that of maternal milk—in nutritive value and ease of digestion.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

Free Samples
with detailed descriptive literature will be sent to any Member of the Medical Profession upon request.

'Byno Eugastrol'

A combination of hog's stomach tissue extract with 'Bynin' Liquid Malt.

The usually recommended daily dose is three tablespoonfuls, which represents an amount of extract equivalent to 100 grammes of fresh stomach tissue.

A very palatable preparation.

In bottles, 4 oz., 10 oz. and 20 oz.

'Kapsol Eugastrol'

Presents hog's stomach tissue extract in the form of capsules, each equivalent to 25 grammes of fresh stomach tissue.

The usual daily dose is four capsules.

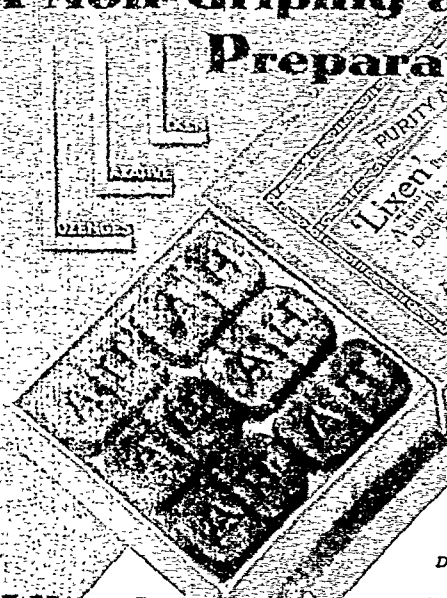
In tins containing 20, 40 and 80 capsules.

Further particulars sent on request.

Allen & Hanburys Ltd., London, E. 2

Telephone: 3201 Bishopsgate (10 lines). *Telegrams*: "Greenburys Edo London."

A Non-Griping and Palatable Preparation of Senna



Contain "Lixen" in a fruit basis.

Really pleasant to take.

Appeal particularly to children.

Each lozenge is equivalent to 6 large senna pods.

In boxes of 12 and 24 lozenges for prescribing.
In bottles of 100 lozenges for dispensing.

Descriptive literature and clinical trial sample will be sent on request.

Allen & Hanburys Ltd., London, E.2.

Telephone: 3201 Bishopsgate (10 lines) *Telegrams*: Greenburys Edo London.

SANDOZ SANDOZ

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the *only* calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

Observations
ON
ANGINA PECTORIS

BY
JOHN COWAN, M.D.
CONSULTING PHYSICIAN, GLASGOW ROYAL INFIRMARY

Angina pectoris is not a specific disease of the heart, but merely a single symptom of varied origin. If there is anything certain about it, it is its uncertainty. The initial seizure may prove fatal, or recurring attacks may continue indefinitely without gravely interfering with the business of life; but sooner or later it causes death. The striking feature of most diseases of the heart, even mortal disease, is the absence of pain. Anguish may be great from shortness of breath, a feeling of suffocation or consciousness of the heart beat, but actual pain is rare. In angina pain is the dominating symptom—"a suffering as sharp as any that can be conceived in the nature of pain"—and often accompanied by something beyond the nature of pain, a sense of impending death. The pain is as a rule related to the chest; it comes suddenly and goes suddenly. This may be the whole feature of an attack.

NATURE AND DISTRIBUTION OF THE PAIN

Angina varies greatly in its severity in different patients. Slight forms are common, the grave ones relatively rare. In the milder degrees it is only a slight uneasiness about the chest, with no particular localization or characteristics. There may be sensations of numbness, deadness, oppression, constriction, or tightness. It has been compared to a constricting band, or the action of pincers on the chest, and is usually described as dull. Whatever its character, in severe cases the agony may be exquisite.

The site of the pain is generally behind the centre of the sternum, but it may be referred to one side of the chest, usually the left. The pain most commonly radiates into the left shoulder and down the ulnar border of the arm as far as the elbow or fingers; less commonly into both arms, and rarely, into the right arm alone. It may pass upwards into the neck or backwards between the shoulder-blades. In exceptional cases it is referred to the epigastrium or the xiphoid cartilage, and consequently ascribed by the patient to some gastric disorder. For a short time after the attacks the affected arm may be weak, it may be so tender that blood pressure examinations are impossible, or it may be insensitive, though this is rare. Attacks of herpes in the painful areas, atrophy of muscles, and vasomotor phenomena such as pallor or cyanosis have been recorded. As a rule the character and the distribution of the pain in successive attacks remain constant.

Distribution of the Pain

	Cases
Substernal	95
Substernal radiating into the left arm	36
Substernal radiating into the right arm	2
Substernal radiating into both arms	24
Substernal radiating into the neck	19
Substernal radiating into the back	8
Chiefly epigastric	11
Chiefly about the shoulder...	5
	200

Coinciding with the pain there is, not infrequently, a feeling of impending death, which may be more overwhelming than the pain itself. This angor animi, as Ryle[1] points out, is not a fear of death, but a sense of impending dissolution, often accompanied by a sensation of constriction of the chest and the feeling that any movement, thoracic or systemic, would prove fatal. Usually associated with pain, it may, however, occur independently—the angina sine dolore of Gairdner. In one attack which we witnessed this angor animi was the prominent symptom, the patient being quite definite that he did not suffer pain. He died three years later from an infarct of the heart. In the typical attack the patient stops and holds on to some support, unable to speak, breathe, or move from the intensity of his distress; his face pale and covered with sweat, or unaltered save for the expression of his agony. The initial attack generally follows physical exertion. Several of our patients suffered for the first time when hurrying to catch a train, walking uphill or against a strong wind, or lifting an unusual weight. But it may ensue on ordinary exertion, particularly shortly after a meal. Emotional disturbance—joy, fear, excitement, fits of temper (as in John Hunter's case)—may also be the exciting cause. Cessation of the exertion is rapidly followed by cessation of the pain, but as time passes slight degrees of exertion or disturbance may bring on an attack.

This angina of exertion must be clearly distinguished from comparable attacks occurring during rest, the angina of decubitus (infarct of the heart). These may arise when the patient is quietly reading; or he may be roused from sleep by the pain. In most instances they succeed attacks of the angina of exertion, but occasionally they come without warning. In a series of 84 cases of infarct this unforeseen catastrophe occurred in 7 cases.

Duration of Attack

The duration of attacks varies. In the angina of exertion the onset and termination are usually abrupt, the seizure lasting from a few seconds to a minute or two. It rarely lasts for more than ten minutes, but we have seen one persist for forty-five. In the angina of decubitus the attacks may recur in quick succession for several hours (status anginosus) or may last for a day or more, notwithstanding liberal doses of opium. The termination of attacks is sometimes accompanied by the passage of large quantities of urine, or eructations; but this is unusual. Following attacks the patient as a rule feels exhausted for a time, and then quite well save for the remembrance of his agony.

Such are the usual symptoms in the initial attacks. Eventually death occurs—instantaneously, after a few minutes of pain, or following a prolonged paroxysm. Rarely, a paroxysm is followed by cardiac failure of the congestive type, unaccompanied, as a rule, by pain.

ETIOLOGY

Angina is more common in men than in women, occurring most frequently in the fifth and sixth decades. Our youngest patient was aged 23; but cases have been recorded at the age of 7 (Stewart) and 12 (Allbutt, Heberden, Wild). It is most common among brain workers, as contrasted with the labouring classes, and in occupations which entail nervous strain. Only 13 of our 200 cases were of the hospital class.

We have failed to trace any special relationship between angina and the infections. Apart from the exanthemata, rheumatic fever was the most common antecedent in this series, but its incidence was small. The association of angina and syphilis is, however, closer. In this series 17 patients were known to have suffered from syphilis and 4 from gonorrhoea, the incidence of venereal disease thus being 10.5 per cent. Only one of these patients was in hospital, where the incidence of syphilis in our wards, as shown by routine Wassermann tests, was 8.6 per cent. in the men and 7.2 per cent. in the women. But several writers have found a higher incidence of syphilis in angina, Huchard reporting its presence in 33 out of 130 cases of angina, and Josué in 30 out of 100 cases.

Syphilis is the common cause of angina before 40 years of age, and is generally associated with aortic valvular disease, the valves and the orifices of the coronary arteries both being affected. In this series the three men aged 30 were all syphilitic. After 40 it is less important. One must remember, however, that angina may occur in rheumatic aortic disease, which was the cause in our patient aged 23.

The recognition by Jenner of the common association of angina and disease of the coronary arteries led to the theory that it was due to this arterial lesion; but it was soon found that the coronary arteries might be grossly diseased without the occurrence of angina, and, conversely, that they might be normal in typical cases. It was then suggested, on theoretical grounds, that angina was due to spasm of the coronary arteries. The discovery that the first part of the aorta was frequently diseased in these cases changed the venue to this part, the pain being ascribed to stresses upon it. It was found, however, that these lesions were not invariable. Attention was then paid to the muscle of the heart; but again it was shown that myocardial lesions were inconstant. It was now apparent that angina could not be due to any specific anatomical lesion, but must be the result of some physiological disturbance of the cardiac muscle. Angina, it was suggested, might be due to distension of the heart, with consequent strain upon the muscle, or to muscular exhaustion, or to strain upon a damaged heart or aorta.

Muscular Anoxaemia

The current theory is that angina, however caused, results from muscular anoxaemia. This theory was first formulated by Allan Burns in 1809,[2] and has been elaborated experimentally by J. A. MacWilliam and W. J. Webster[3] in 1923, and clinically by C. S. Keefer and W. H. Resnik[4] in 1928.

Allan Burns's statement may be quoted:

"In health when we excite the muscular system to more energetic action than usual, we increase the circulation in every part, so that to support this increased action the heart and every other part has its power augmented. If, however, we call into vigorous action a limb round which we have, with a moderate amount of tightness, applied a ligature, we find that then the member can only support its action for a very short time; for now its supply of energy and its expenditure do not balance each other; consequently it soon, from a deficiency of nervous influence and arterial blood, fails and sinks into a state of quiescence. A heart, the coronary arteries of which are cartilaginous or ossified, is in nearly a similar condition. It can, like the limb begirt with a moderately tight ligature, discharge its function so long as its action is moderate and equal. Increase, however, the action of the whole body, and along with the rest that of the heart, and you will soon see exemplified the truth of what has been said; with this difference, that as there is no interruption to the action of the cardiac nerves the heart will be able to hold out a little longer than the limb."

MacWilliam applied a tourniquet to the arm and noted the results: (*a*) so long as the forearm muscles remained inactive, and (*b*) when these muscles were thrown into action. As he found that the symptoms might, in part, be due to turgescence of the limb if the constriction was suddenly applied, he made the limb ischaemic by means of an elastic bandage, applied first to the fingers and the hand, and only removed after the application of the tourniquet. In a limb thus treated and kept immobile no notable result followed for the next twenty minutes, save for some coldness in the part, an inclination to shift the position of the arm, and a certain amount of discomfort at the site of the constriction. Muscular activity of the forearm muscles, however, rapidly produced marked discomfort. Fatigue, as measured by the number and force of contractions executed within a given period, was readily produced, the fatigue point being reached in one-half or one-third of the time required in the normal limb. The forearm, too, rapidly became painful, and, as the fatigue point was approached, so acutely painful that the desire for relief became urgent. Cessation of the exercise did not relieve the pain, which ceased only after relaxation of the tourniquet and the return of blood to the ischaemic muscles. Though relief of pain was thus readily afforded, fatigue was still apparent, and passed off only after some interval of time.

"It need hardly be pointed out that the foregoing observations have a close bearing upon the problems associated with the production of pain in angina pectoris, showing as they do how readily acute pain can be excited in skeletal muscles working with lack of blood supply, the pain developing while the contractile power, though to some extent weakened, is still sufficient to execute movements of considerable force and energy—that is, long before complete fatigue."

This experimental work is supported by clinical observations. In intermittent claudication severe pain and weakness in the muscles of the legs may ensue on exertion and cease when the exertion ceases. In senile gangrene from obliteration of an artery pain is constant; and in cases of embolic arterial block—for example, in mitral valvular disease—pain is always present if a limb is involved. We have notes of seven cases of this kind where gangrene followed; and in a case where gangrene resulted from thrombosis of a popliteal aneurysm acute pain in the leg occurred suddenly, and persisted. Intermittent claudication is exactly comparable to angina of exertion; senile gangrene and embolic block to angina of decubitus (infarct).

Keefer and Resnik[4] analysed a series of 399 cases of angina in which post-mortem examination had been made. In 380 cases the coronary arteries were diseased, and in the remaining 19 the aortic valves were incompetent. It may readily be assumed that, in certain circumstances, all these cases suffered from anoxaemia of the myocardium. Disease of the coronary arteries must necessarily limit the flow of blood to the heart, which may be sufficient for the muscle working quietly, but be inadequate to meet any additional exertion. In aortic incompetence the diastolic blood pressure is low, and, as the muscle of the heart is supplied with blood during diastole, its blood supply even at rest must be limited, and may become insufficient if extra exertion demands a more ample supply. It is in the syphilitic cases that angina is most common, for here aortitis is the rule, and the coronary orifices are frequently involved in the lesion. The resulting ischaemia produces pain. There is no essential difference between the angina of exertion and that of decubitus. In the first, the ischaemia is relative and intermittent; in the second, absolute and permanent. If the circulation is merely impaired, symptoms will only ensue when exertion renders the parts relatively ischaemic, while if the block is complete the symptoms will continue for an indefinite period.

A similar line of reasoning explains the occurrence of angina in all the other conditions with which it may be associated. It occurs, rarely, in severe anaemias in which ischaemia might readily occur. But the ischaemia in these cases is general and affects all the tissues of the body, and the general debility as a rule prevents exertion capable of throwing undue strain upon the heart. In mitral valvular disease and congenital heart disease venous congestion, if present, is general, and the whole heart fails, dyspnoea checking the exertion before the painful stage of ischaemia develops. In coronary disease only a part of the heart is concerned, the greater bulk remaining unaffected. The heart as a whole can thus respond effectively to a demand for increased activity, but the part whose blood supply is limited now becomes ischaemic, and painful sensations arise. Thus angina can coexist with the possession of adequate power by the heart as a whole. In one of our cases the blood pressure at rest measured 280 mm.

Post-mortem Appearances

In this series a post-mortem examination was obtained in 13 cases. Of these, 12 presented infarcts or fibrosis in the muscle, the coronary arteries being extensively diseased. The other patient, a man aged 47, who had been out work for a couple of months on account of shortness of breath and palpitation on exertion, had his first attack of angina when walking, and died two days later during another attack. There was well-marked syphilitic aortitis above the aortic cusps, which were thick and shortened, with a slight recent acute endocarditis superadded. The orifices of both coronary arteries were involved in the aortitis and greatly narrowed. The arteries in their course were normal and the muscle of the heart intact. In two cases there was rupture of the heart.

Vasomotor Disturbances

Vasomotor disturbances not infrequently accompany attacks of angina. In two of our patients the blood pressure during an attack measured 160 mm. Hg, and in the intervals 120 mm. in one case, and 130 to 140 mm. in the other. In another patient an "interval" blood pressure of 140 mm. Hg rose to 190 mm. during an attack. Sometimes attacks occur during a period of high blood pressure, and cease with its disappearance. A stoker, aged 50, caught cold, and a week later began to suffer from attacks of angina on exertion. After a few days he entered hospital and his attacks ceased. His blood pressure, on admission 215 mm., fell steadily, reaching 145 mm. on the fifth day, and 135 mm. before discharge. At the same time his left heart, which on admission had been slightly dilated, recovered its tone. He was in hospital three and six years later suffering from bronchitis and gastritis. The angina had not recurred. His systolic blood pressure was then between 135 and 150.

Some patients who suffer from angina tell us that, while they can in favourable circumstances undertake considerable exertion without distress, attacks ensue if they are exposed to cold, if exercise is taken immediately after food, or if they are subjected to nervous strain. The cause is to be found in vasomotor alterations in the distribution of the blood. Everyone knows that the increased supply of blood to the digestive organs after a meal produces mental languor as the result of the lessened supply available for the brain. Cold, food, emotion, are all factors which influence the blood pressure and the distribution of the blood throughout the body.

Professor MacWilliam points out another possible factor.

"So far as my observations go there is not necessarily such rise of blood pressure on exposure to cold as would throw a decidedly greater strain upon the heart. It seems to me that some transient attacks of pain, with no obvious and sufficient exciting cause, probably depend upon a central nervous factor, an increased susceptibility to pain from irritant influences arising in the heart. Exposure to cold, for instance, often tends to excite neuralgic pains, anywhere, in a susceptible subject."

Such an explanation seems feasible. Many patients are highly strung and intolerant of discomfort, and some are quite unable to bear a blood pressure examination of the left brachial artery. Several, too, have told us that their attacks cease as soon as they have swallowed a tablet of trinitrin, before any effects of the drug could have been manifested.

Intoxications

In rare instances angina seems directly related to feelings of constriction experienced in other situations; tobacco, tea, and coffee being the common offenders. One of our patients suffered from exophthalmic goitre, two from myxoedema; in these toxic causes of impending asphyxia were present. F. R. Fraser, however, informs us that he has never seen angina pectoris in Graves's disease, although he has frequently experienced it himself. Rylet points out that in myxoedema angina is very rare in spite of the presence of arterial degeneration. Usually associated with arterial degeneration, the association was probably accidental. We have seen a clear case due to tobacco.

The patient was a healthy, well-built man, aged 21. His first attacks had occurred six years previously, when serving in the Army, from which he was, in consequence, discharged. At that time he smoked heavily, but subsequently gave it up until shortly before his admission to hospital. The attacks at once recurred. The pain, he said, was never very severe, but sufficient to make him stop work. It was substernal, and occurred only when he was at his work, which was arduous. For a week before admission the pain had been increasing in severity, and he had become short of breath on exertion. His organs seemed sound. His pulse rate on admission was only 40 per minute, but the heart's action otherwise was normal, and the blood pressure within normal limits. His fingers showed a fine, rather irregular, tremor. In a few days his pulse rate rose to 68, and all discomfort disappeared.

Nicotine has a powerful action upon nerve cells, producing an initial stimulation followed by paralysis. At first the pulse rate slows and the blood pressure rises; and this is followed by an increase in the pulse rate and a fall of blood pressure, due, in part at any rate, to direct action of the drug upon the myocardium (Cushny).

THE NERVE SUPPLY OF THE HEART

The exact details of the nervous supply of the heart are as yet undetermined. The pathway of the efferent nerve fibres is fairly clear; the inhibitory impulses travel

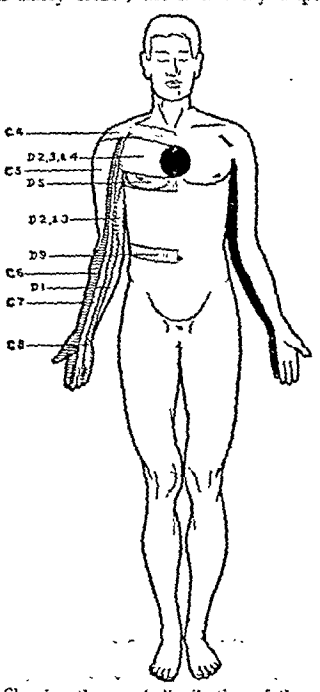

FIG. 1.—Showing the usual distribution of the pain in angina and the relative spinal distribution.

along the vagus nerve, while the accelerator impulses, issuing from the upper dorsal segments of the cord, pass through the inferior cervical ganglion and the inferior cardiac nerve, and perhaps, in part, through the middle cardiac nerve. The pathway of the afferent fibres is less clear. The depressor impulses pass upwards along the vagus nerve, but the other afferent impulses pass through the sympathetic system, entering the cord through the upper five or six dorsal roots. There is no evidence of their passage through any cervical root, or the vertebral nerve (Langley).[3]

The reason for the characteristic distribution of the pain in angina is thus apparent. The cardiac sensations enter the upper dorsal segments of the spinal cord. Th peripheral representation of these segments is shown i Fig. 1. Extreme stimulation of the dorsal segments le

to an overflow of the stimuli to adjacent segments and so to radiation of the pain into the neck and epigastrium.

DIAGNOSIS

The diagnosis is established by the history of attacks of substernal pain occurring on exertion and relieved by rest, with or without the characteristic radiations and angor animi. The distribution of the pain varies in different patients, but it is never referred to the apex of the heart save as a part of a widespread distribution. Pain in this area alone, a common complaint in stout women, is due to causes other than cardiac. Some are gastric in origin, some due to hyperaesthesia of the breast, some to fibrositis or strain of the pectoral muscle.

The majority of our patients were at work, apparently in their usual health, at the onset of their symptoms, only 44 being under medical care at the time. Of these the largest group complained of cardiac symptoms, a lesser number suffering from symptoms due to arterial or renal disease.

Although the majority of our patients made no complaint prior to the onset of their anginous attacks, subsequent examination, as a rule, revealed pathological changes. In 90 cases the heart was enlarged ; in 83 of 136 cases the blood pressure was over 150 mm. Hg, the extremes being 105 and 280 mm. In 14 cases the aortic valves were incompetent, and in 45 mitral murmurs were present though not necessarily due to valvular disease. One patient had mitral stenosis. Apart from murmurs the cardiac sounds were often abnormal, the first sound being weak, muffled, or distant, the second sound accentuated or intoned, suggesting myocardial or arterial disease. The electrocardiograms were frequently abnormal. Out of 122 cases the QRS complex was abnormal in 16 ; T-waves were normal in 46 cases, inverted in Lead I in 39, and in Lead III in 37 cases. Heart-block was present in 5 cases, bundle-branch block in 8, extrasystoles in 13, fibrillation in 4 cases, and irregular rhythm in one. In the exceptional case the most careful examination may fail to reveal any abnormality, though as a rule some deviation from the normal is revealed. It may seem difficult in such cases to relate the pain of angina to the heart, but a little consideration shows the reasons. The cause of the symptoms is insufficiency of the cardiac blood supply from narrowing of the arteries at their orifice or in their course, and neither of these lesions has distinctive physical signs. Syphilitic aortitis is often a post-mortem discovery, as it fails to show itself unless "something happens"—incompetence of the aortic valves, narrowing of the coronary orifices, or aneurysmal dilatation. A purely local lesion of the coronary arteries will only manifest itself by physiological disturbances. In one of our patients who died of angina, due to coronary stenosis at the orifice from syphilitic aortitis, the heart itself was quite sound. Arterial disease is usually associated with high blood pressure, renal disease, syphilis, etc., which present their own characteristic signs. The combination of aortic valvular disease and angina always strongly suggests a syphilitic origin, especially in men under 40 years of age, though it may occur in cases of rheumatic or other origin.

PROGNOSIS

Most patients with angina die more or less suddenly. In experimental ligation of the coronary arteries in animals, the cardiac action becomes irregular from extrasystoles, which are followed by tachycardia, ventricular fibrillation, and death. In some cases of angina the cardiac action rapidly weakens—the pulse rate usually increasing—and failure ensues. Life to the anginous patient is uncertain, but may be prolonged for years. Dr. Arnold died in his first attack ; John Hunter had angina twenty years before he died. Two of our patients died at the age of 76—one twenty years, the other fourteen years, after the first attack. Another died at the age of 70, thirty years after the occurrence of Stokes-Adams attacks, due to heart-block which persisted unchanged. Several patients are working, even playing golf, after five and ten years. Even those who have had definite infarcts may make a good recovery. One of our patients worked hard for five of the seven years which elapsed between his infarct and his death, and one of A. G. Gibson's patients lived an active life for five years after his attack, dying at the age of 72.

The best outlook is that of the toxic and anaemic group if the cause of their symptoms can be removed. Of the other groups, those with a high blood pressure, those with aortic valvular disease, those with a low blood pressure, in order. Patients with high blood pressure can, as a rule, be relieved by appropriate treatment. Syphilitic valvular disease can be helped by specific treatment. Those whose hearts are weak, without obvious cause and so in all probability from coronary stenosis, are unlikely to obtain satisfactory remission of the underlying pathological cause.

Two other factors are important: the exciting cause of the original attack, and the mental attitude of the patient towards his difficulties. It is obvious that if an attack supervenes on trivial provocation it is more likely to be due to a gross lesion than one which follows severe physical or mental strain. The mental attitude is equally important. Can the individual react to his limitations successfully, adapting his life to his altered equilibrium, or will he fail to do so, and continue to run his usual course? An attack of angina gives warning that the pace in future must be lessened.

TREATMENT

The general lines of treatment are well defined. The treatment of the toxic and anaemic cases is obvious ; and that of aortic valvular disease, with angina, is similar to that of the cases without anginous symptoms. In the cases due to coronary disease every endeavour should be made to *prevent undue strain upon the heart until satisfactory anastomoses have had time to form* and to supply the myocardium with sufficient blood. The coronary circulation is ample, and free anastomoses exist between the main arteries, and between their branches. An attack of angina indicates that some arteries are narrowed, and that closure may occur. Functional overactivity of the heart will lead to disaster. In angina confinement to bed is not always helpful, though sometimes useful from the psychological standpoint ; but activities must be kept at a low level for a prolonged period. All other treatment is subsidiary. In patients with high blood pressure increased elimination must be secured by the usual methods. In syphilitic cases specific treament must be instituted. In patients with weak hearts stimulant treatment is indicated.

The treatment of a paroxysm is necessary but of less importance than its prevention. Angina is a danger signal, a sign of some harmful activity, and if we make the patient insensitive to his discomforts he will soon kill himself. If the blood pressure is raised during attacks the nitrites are useful, but they are useless if the blood pressure is not raised. Sedatives should be given without hesitation, morphine being the most effective. Chloroform is sometimes necessary.

Surgical Treatment

The surgical treatment of angina is still in the experimental stage, and we doubt if it will ever prove of much value. All surgical treatment aims at the relief of cardiac pain ; but pain is a useful danger signal, an

indication to the patient that his current activities are harmful and must be stopped at once, or death will ensue. But there remain a few patients whose sufferings are so severe that relief at any cost seems desirable.

Numerous operations on the cervical nerves and ganglia have been performed with the object of severing the sensory communications between the heart and the brain; but so far as our knowledge goes these operations are based upon erroneous theories. The sensory tracts run into the upper dorsal segments of the spinal cord, and not along the neck. It is known that left-sided pain is referred from the heart to the upper five or six segments, the chief pathway being along the inferior cardiac nerves, the stellate ganglion, the vertebral sympathetic ganglia, and the white rami communicantes to the spinal cord. Subsidiary pathways may exist along the middle cardiac nerves and the lower cervical sympathetic trunk to the stellate ganglion; and directly from the heart to the upper dorsal vertebral ganglia[4] (Fig. 2).

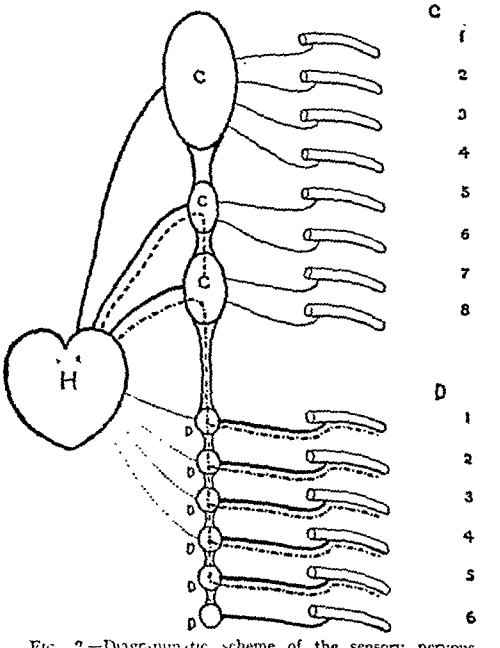

FIG. 2.—Diagrammatic scheme of the sensory nervous connexions of the heart. C, Cervical sympathetic ganglia; D, Dorsal sympathetic ganglia; D, Dorsal nerve roots; — — — — —, Main route of sensory impressions; - - - - - -, Secondary route; . . . . . Direct route.

The pathways might be blocked by: (1) removal of the stellate and the upper dorsal vertebral ganglia; (2) section or block of the rami communicantes; (3) section or block of the posterior nerve roots.

The least dangerous procedure seems to be alcohol injection of the rami communicantes, of which favourable results have been reported.[7] James C. White has now operated upon 17 patients who were subject to severe and frequent attacks of angina which resisted medical treatment. All recovered from the operation without serious trouble, the only unfavourable sequels being attacks of pleurisy in three cases, which rapidly subsided. In 7 cases complete relief from the left-sided pain followed, and in 5 the relief, while not complete, was considerable. In 3 cases improvement was slight, and in 2 cases no improvement resulted. Five patients have been able to return to work. He states that shortness of breath, peculiar sensations, without pain, in the region of the heart, or mild attacks of right-sided angina, have always afforded sufficient warning to the patient that the danger zone of exertion was being approached. The upper dorsal ganglia were removed in 3 patients whose general condition permitted an open operation by Henry's route. All these patients made good recoveries, and the pain was completely checked.

Eight of these patients have died, seven of them within a year of the operation, one from an empyema, the others from cardiac causes. One patient is alive three years after operation, and two patients two years after operation. Such results must be expected, for the operation is merely palliative and in no way curative. But relief from severe recurrent pain, even if of short duration, may be an inestimable boon to some patients.

We have great pleasure in acknowledging the kindly assistance of many friends; in particular, G. B. Fleming, F. R. Fraser, D. Dale Logan, G. D. Logan, J. A. MacWilliam, J. K. Rennie, James C. White, and Farquhar Macrae.

THE DEVELOPMENT OF THE SCIENCE OF NUTRITION IN RELATION TO DISEASE*

BY

J. B. ORR, *D.S.O., M.C.*, M.A., M.D., D.Sc.

THE ROWETT RESEARCH INSTITUTE, ABERDEEN

In the last twenty years there have been rapid developments in our knowledge of animal nutrition. This knowledge continues to accumulate at an increasing rate; it has such a direct and important bearing on the prevention or cure of disease that nutrition may now be regarded as a new branch of medical science.

HISTORY

It is interesting to contrast the outlook of last century with that of the present day. At the beginning of the period our ideas were little in advance of those held by the Greeks. Writers still believed that there was only one nutrient substance common to all foodstuffs. Early in the century it was established that heat and muscular energy had their origin in a process of oxidation, and calorimetric studies had shown that the human body obeyed the law of conservation of energy. By the middle of the century, chemists had differentiated food constituents into three "proximate principles"—proteins, fats, and carbohydrates—all yielding energy. At the end of the century, the energy values of different foodstuffs, and the energy requirements of the human body under different conditions, were fairly well known, and the position of the calorie as the symbol of nutrition was well established. Proteins were recognized to be of special value, being necessary for construction in growth and repair of "tear and wear" of the tissues. Dietaries were calculated in terms of calories and protein, and studies in the physiology of nutrition were concerned mainly with metabolic processes involving exchanges of energy, and with the metabolism and chemistry of the proteins and their derivatives, and to a lesser extent of

* Summary of a British Medical Association Lecture delivered to the Dundee Branch on March 11th.

the fats and carbohydrates. With knowledge at this stage it was inevitable that workers should tend to over-emphasize the analogy between the body and a machine as energy converters, and to regard the provision of sufficient fuel for energy and material for repair as the only aspects of nutrition which were of practical importance. Although the limitations of this view are now recognized, we must not underestimate the importance of the work done in the nineteenth century. The succession of investigators from Lavoisier to Fischer established the main principles and laid the foundation of the science of nutrition. Nor can we assume that the research on energy exchange and protein metabolism is finished. Although at the present time popular interest has moved to the newer aspects of the subject dealt with here, there is still work of great scientific interest and practical importance being done on energy exchange and the metabolism of the proteins, fats, and carbohydrates.

The main feature of the work of the present century has been the shift of the centre of interest in nutrition from quantity to quality. The epoch-making experiments on vitamins, and the tardy recognition that a diet may be adequate in calories and protein, and still deficient in some of the inorganic constituents, opened up new fields of research. The discovery that a slight difference between two diets, which could neither be detected by the eye nor determined by chemical analyses, might mean the difference between life and death, completely altered our point of view, and of necessity our methods of work. In addition to chemistry and mathematics we had to resort to the biological test to determine the value of foodstuffs. Calculations based on the results obtained with the calorimeter and the test tube have been supplemented by clinical observations; the adequacy or inadequacy of a diet is now judged by observations on the state of health, the presence or absence of symptoms of disease, the rate of growth, and powers of reproduction. In this way, modern nutritional studies are tending more and more to become of the same nature as clinical studies, and so the gap that existed at the end of last century between the biochemical laboratory and the hospital ward is now being bridged.

RESULTS OF MODERN INVESTIGATION

Let us review briefly the main results obtained in experimental work on animals by these newer methods of investigation. The spectacular effects in diseases arising from vitamin deficiency, such as scurvy, beri-beri, and rickets, are so well known that they need not be further discussed. It is completely established that these diseases can be produced or prevented at will in experimental animals by introducing or withholding certain nutrients from the ration. The work on diseases due to mineral deficiencies which has been done on the larger domestic animals is not so well known to the medical profession. Owing to the very rapid rate of growth of modern improved breeds the mineral requirements of the larger domestic animals are relatively high, and consequently the effects of deficiency are easily demonstrated. Rickets and osteoporosis can be produced by deficiency either of calcium or of phosphorus. In cattle, a condition characterized by inco-ordination of movement, and later by paralysis accompanied by the usual signs of malnutrition, is produced on a phosphorus-deficient diet. In certain districts, goitre accompanied by a high mortality rate in the young occurs, and is prevented by the administration of iodine. Anaemia, which can be prevented by administration of iron, is found both in cattle and pigs on certain diets. All these diseases in domestic animals, which have been produced and studied under experimental conditions, are known to occur, and in some cases to be common under ordinary conditions.

The discovery that these deficiency diseases are due to the lack of specific nutrients, whether vitamins or minerals, was in itself a great achievement, but the practical importance of this work is much greater than the mere cure or prevention of these pathological conditions. In experimental studies with animals it has been observed that there are all stages of malnutrition ranging from what we regard as normal health to that in which the gross and terminal symptoms appear. The signs of minor degrees of deficiency are now well known, and need not be enumerated. Some of the signs are common to, and occur in, the early stages of nearly all deficiency diseases. Generally they are indications of lowered vitality. Young animals have a slower than normal rate of growth, the reproductive powers of adults are defective, the coat is dull and lustreless, appetite is decreased, and the animals show, instead of the *joie de vivre* of the perfectly healthy animal, lethargy and other signs of premature senility. A point of practical importance which should be emphasized is that when these diseases occur under ordinary conditions the number of animals suffering from minor degrees of deficiency usually far exceeds the number showing the gross signs of disease.

Increased Susceptibility to Infections

There is another result of dietary deficiency which is equally far reaching in its practical importance. It has been noted by many workers that susceptibility to certain infectious diseases is definitely greater in groups of animals on deficient diets than in comparable animals on complete well-balanced diets. Classical examples of this are the development of xerophthalmia in rats, and epithelioma contagiosum in fowls, in deficiency of vitamin A. It has been repeatedly noted that animals on diets deficient in the fat-soluble vitamins have a high proportion of deaths from respiratory and alimentary infections. It is believed by some (though we lack definite data on the subject) that in deficiency of calcium and iron there is increased susceptibility to pulmonary infections, and recent work on cattle in South Africa seems to indicate that deficiency of phosphorus increases the death rate, apart from the deaths due directly to styfsiekte or lamsiekte, the direct or indirect cause of which is phosphorus deficiency. The information obtained from these observations warrants us accepting, as a working hypothesis, the view that in animals suffering from even minor degrees of deficiency, resistance to organisms normally present in the body may be reduced, and hence bacteria, which, in an animal on a perfect diet might remain non-pathogenic, find in the abnormal tissues and fluids of the host a favourable medium in which their activities can give rise to the specific signs of infection. This aspect is only beginning to be explored. It is an intricate subject to study, because there are involved such a large number of factors, some of which are difficult to control.

It is impossible here to do more than indicate the nature of the work being done in this field of research. There are three important lines: attempts are being made to ascertain (1) the changes which occur in the composition of the blood under different dietary conditions; (2) the effect of diet on immunological reactions; and (3) the effect of diet in altering either the nature of the flora or the pathogenicity of the existing flora in the respiratory, intestinal, and other areas in the body.

Diet and the Composition of the Blood

Biochemical examination of the blood of experimental animals has shown that the level of some of the mineral elements is by no means so constant as was at one time thought. For example, it has been shown that the feeding of a diet low in calcium and high in phosphorus results in a lowering of blood calcium and a rise of blood

inorganic phosphorus to an extent which was thought impossible a short time ago. In an experiment on sheep at present being carried out, it has been found that the blood calcium has been nearly halved, and inorganic phosphorus more than doubled. On the other hand, in cattle suffering from aphosphorosis, the inorganic phosphorus in the blood may be less than half the normal. These results in large animals are on the same lines as those which have been previously noted in rats. Studies are also being made on the influence of the diet on the alkali reserve of the blood, which, as is well known, can be altered within fairly wide limits by medication.

These experimental studies in which workers are seeking for a correlation between composition of diet and composition of blood are already giving fairly definite results in so far as the inorganic constituents are concerned. Comparatively little headway has been made, however, with the organic constituents, though observations on these are being carried out.

Diet and Immunological Reactions

Side by side with this inquiry by chemical methods, investigations are proceeding on the effect of diet on immunological reactions. Here, also, positive results are being obtained. Thus, in observations on agglutinin formation in guinea-pigs and rats inoculated with *B. typhosus*, it has been noted that there is a significantly low titre in animals on a diet deficient in phosphorus, and both agglutinins and bacteriolysins against *B. typhosus* in rats are reduced on diets deficient in vitamins A and D, or B and E. In work on sheep very marked changes have been found in animals transferred from deficient experimental rations to pasture feeding.

Diet and the Flora

The effect of diet on the flora in different areas of the body has been studied in the case of the intestine for many years. It is well known that the reaction of the intestinal contents can be altered by the food, and that such alterations cause changes in the bacterial flora. Of special interest are some observations on the effect of changes in the reaction of the blood. Most bacteria flourish best in a slightly alkaline reaction. It has been observed that treatment which tends to alter the *p*H of the blood to the acid side, or which lowers the alkali reserve, reduces antibody formation in response to infection. Reduction of bactericidal power has been obtained by an administration of hydrochloric acid, and by section of the spinal column, which causes a fall in blood alkalescence. On the other hand, a directly reverse effect has been noted in a recent study of wound infections. In controlled experiments in which alkali reserve, *p*H of blood, and *p*H of wound exudate were estimated, it was found that a rise in the alkali reserve above normal was associated with an increase in the number and virulence of the bacterial flora, and that a shift to the acid side resulted in a reduction of the number of infecting organisms. If these results be confirmed they show that the alkali reserve, which can be controlled by the diet, is an important factor in resistance to infection, and that changes in its level affect differently the individual types of bacteria.

Even this brief consideration of work along these three lines is sufficient to show that we have here a most promising field of research. The scrappy data which we have already obtained prove that the nature of the diet affects the powers of the body fluids to deal with infection, and, what is equally important for the success of further work, that chemical analyses of the blood and serological tests give us a means to make a quantitative assessment of the effect.

In view of the vast extent of this field, however, we cannot claim to have done more, so far, than make a few preliminary observations. Even the meagre results obtained have not yet been all confirmed, nor is their full significance clear. More experimental work is needed before we can begin to link up the biochemical, immunological, and clinical data to see what correlation exists between different dietary factors, the chemical composition of the blood, its immunological reactions and susceptibility to different pathogenic organisms. When we *do* reach that stage we will have greatly increased our powers to prevent and cure disease. We will be able, by dietary measures, to keep animals in such a state of health that when invasion by organisms takes place the *vis medicatrix naturae*—the only therapeutic agent of any real value—will be able to exert its full beneficial influence, unhampered by abnormal conditions of body fluids and tissues due to faulty diet.

NUTRITION AND THE HUMAN BEING

So far we have confined the discussion almost exclusively to the results of experimental work on animals. Let us consider to what extent our findings are applicable to human beings. We know that deficiency diseases such as scurvy and rickets occur in the human being, and are cured by the same dietary manipulations as are found to prevent or cure them in animals, and there is abundant evidence to show that when these diseases appear, minor degrees of malnutrition are prevalent among the whole population living under the same dietary conditions as those suffering from the gross symptoms of disease. Thus it is now recognized that beri-beri is but the terminal gross manifestation of deficiency disease, the actual outbreaks being merely superimposed on a condition of chronic ill-health.

We cannot put groups of human beings under experiment to test directly the effect of diet on the chemical composition and serological reactions of the blood and on resistance to disease. Recently, however, observations have been made on two tribes in Africa, living under conditions almost as favourable for the study of this problem as if the diets had been prearranged. The diet of one of the tribes consisted chiefly of cereals, and was found to be deficient in calcium, and almost certainly in vitamins A and D. The diet of the other tribe, consisting largely of milk, meat, and raw blood, though defective in other respects, was rich in those nutrients deficient in the former tribe. Unfortunately, samples of blood could be obtained only from members of the cereal-eating tribe, but the incidence of disease was studied in both. It was found that the average calcium content of the blood serum in the tribe on the cereal diet was only 9.4 mg., compared with an average of 11.4 mg. for Europeans living in the same district. A survey of the incidence of disease showed that in the tribe with the cereal diet, pulmonary conditions, bronchitis, and pneumonia accounted for 31 per cent. of all cases of sickness, tropical ulcers 33 per cent., and phthisis 6 per cent., compared with a percentage of 4, 3, and 1 respectively in the tribe with the meat, milk, and raw blood diet. In the latter tribe the chief disease was rheumatoid arthritis. There is obviously in these two tribes a correlation between the nature of the diet and the resistance to disease.

Some surveys on the incidence of disease in this country show a social distribution which indicates a possible connexion with diet. In a recent study in which the population was divided into five social classes, ranging from the professions and higher ranks of business to unskilled labour, it was found that at ages between 20 and 65 the death rate from respiratory diseases was 3.3 times, from heart disease 2.24 times, and from cancer

1.54 times as high in the fifth class as in the first class. There are here other environmental factors which complicate the issue, but the fact that the diets of the professions and higher ranks of business life are so much more varied and better balanced than the cheaper, carbohydrate-rich diet of unskilled labour, suggests that diet may be a factor, and warrants further study.

If malnutrition with increased susceptibility to certain diseases commonly exists, it should be possible to show that dietaries in common use are faulty. Unfortunately, we have too little information on the requirements for either vitamins or minerals, the two classes of nutrients to which our discussion has been limited. Nor have we much exact information as to the amount of intake of these nutrients. We have had many dietary surveys of the protein, fat, and carbohydrate intake, but very few on those dietary factors which we are finding of so much importance for health. One such survey, recently completed in Scotland, has yielded results which suggest that in a large proportion of families the diet does not supply a sufficiency of certain minerals to maintain the maximum rate of growth. In 607 families in the seven largest Scottish towns it was found that in only two cases was the energy value of the diet below 2,000 calories per man. There was thus no indication of any gross undernutrition. If we take Sherman's figures, however, which are almost the only reliable data we have on the subject, as a true indication of the requirements of the growing child for calcium and phosphorus, we find that there was a deficiency of calcium in 24.5 per cent. and of phosphorus in 23 per cent. of the dietaries. The position was worse in the case of iron. In 61.6 per cent. of families the amount of iron in the food was below that regarded by those who have worked on the subject as the optimum intake. In 41 per cent. of the families the protein intake, though sufficient for adults, was below the optimum requirement for growth in children.

We must not place too much importance on these findings, since far too little work has been done to enable us to know, with any degree of certainty, the requirements of the child for these food constituents. The results, however, appear to be of some significance when they are considered in the light of a test on the value of an increased consumption of milk in children drawn from the households of which the survey was made. In that test it was found that the addition of milk, either whole or separated, during a seven months' experimental period was accompanied by a rate of growth as indicated by increase in both height and weight about 20 per cent. greater than that in the children not receiving the extra milk. Clinical examination of the children showed that the increased rate of growth was accompanied by an improvement in the general condition. The improvement could not have been due to an increase in the number of calories, because it was found that in different groups of children who received carbohydrate and fat-rich biscuits of equal caloric value to the milk, there was no improvement in condition or increase in rate of growth. This is in accordance with the finding of the survey that the calorie intake was, on the whole, ample. It may be assumed that the effect of the milk was due to the fact that it supplied nutrients which the survey showed to be otherwise deficient.

CONCLUSIONS

We have here brought together some of the more striking results of experimental studies on animals and of observations on human beings, to illustrate the nature of the recent developments of our knowledge of nutrition in its relation to disease. It is obvious that the progress already made in this new field of study is of great importance in both preventive and therapeutic medicine. The principles of some of the results have been applied in stock farming, and have led to a reduction in disease and to increased output by farm stock. In human medicine the effects of their application on children, who are more likely to suffer from deficiencies than adults, are well known, especially as regards the cure and prevention of rickets and scurvy. The spectacular results obtained in the United States and Switzerland in the prevention of endemic goitre and cretinism by iodine medication, and such facts as the prevention of beri-beri by the improvement of rations through the substitution of unpolished for polished rice, are now common knowledge. The recent work on the influence of the acid-base ratio of the diet on chronic nephritis gives an interesting example of the application of nutritional science to therapeutic ends.

The potential value of the information acquired from the research work we have described, as well as the practical results, give every encouragement to extend our studies. Some of the lines along which work should be conducted are clear. We need more information dealing with the amounts of different nutrients required for optimum growth in children, and for the maintenance of health, and also as to the amounts of these nutrients present in dietaries in common use. A concerted international effort to elucidate whether there is a correlation, and, if so, to what extent, between dietary habits, physique, and incidence of disease in the different populations throughout the world would yield results of fascinating interest. The League of Nations has recently carried out a survey of the diet of Japan in relation to beri-beri. The wider problem of the world correlation between diet and health appears to be of sufficient importance to warrant the attention of that council.

In addition to such dietary studies, an urgent need exists for more clinical research on nutritional lines. There are a number of diseases of which the main symptoms are those of disturbance of the normal digestive or metabolic processes—for example, gastric and duodenal ulcers, constipation and its sequelae, rheumatism, anaemias, high blood pressure, and cardiac and nephritic disorders. The etiology of these remains obscure. It has been suggested that they originate in long-continued errors of diet. As a matter of fact, we have very little definite evidence to show to what extent hereditary, nutritional, and other factors are involved. An extended series of studies of previous nutritional histories, of the condition of the circulating fluids, and of the influence of dietary factors on the course of these diseases might throw much-needed light on their etiology.

Future advances in the study of nutrition as applied to human medicine will undoubtedly be made through team work, especially of biochemist, immunologist, and clinician. An essential feature of such work should be the co-ordination of research on the larger domestic animals with that on human beings. The main problems are essentially the same in both fields, and, indeed, some of the diseases on which more work is urgently required are common to man and the higher mammals. For example, osteoarthritis is as common in the horse as in man, and simple goitre appears to occur in all mammals in certain areas where its distribution is coincident with that of endemic goitre in the human population. The nutritional factor in resistance to tuberculosis, which is now recognized as being of importance in human medicine, is equally important in the dairy cow. It is to be hoped that, in the future, in those comprehensive studies which are initiated or supported by the State, there will be co-operation, not only between individual workers in different branches of science, but also between medical and veterinary research institutions and organizations.

THREE CASES OF PSITTACOSIS WITH TWO DEATHS

BY

H. R. FISHER, M.B., CH.B.LIVERP.

AND

R. J. HELSBY, *M.C.*, L.R.C.P., L.R.C.S.ED.

It has been generally accepted that psittacosis is usually caused by contact with parrots, and it must be admitted that the human cases of the disease that were being so regularly reported in the medical journals during the early part of 1930 appeared to cease after the regulations of the Ministry of Health prohibiting the importation of parrots came into force in May of that year. The small outbreak described below suggests, however, that psittacosis may still be occurring unrecognized, and that the possible contact with birds of patients suffering from symptoms suggestive of an atypical pneumonia or enteric fever should not be overlooked, especially as these three cases show the very real danger of human case-to-case infection in psittacosis.

We were fortunate in obtaining the collaboration of the Ministry of Health in the investigation of these cases, and also of Dr. Dorothy S. Russell and Dr. S. P. Bedson of the London Hospital, both of whom have kindly contributed notes on the pathological and bacteriological findings, which appear below; and we wish to record our appreciation of the assistance given to us.

On October 21st, 1930, one of us (H. R. F.) returned from a holiday and found that his locumtenent had been greatly puzzled by a case which eventually appeared to have been one of pneumonia.

CASE I

The patient, a lady, aged 45, on a visit with another lady, began to feel unwell on October 11th, the day after her arrival. During the first four days of her illness, the only symptoms were severe headache, pyrexia (103° F.), and quickened respirations; later she had constipation, followed, after a dose of Epsom salts, by a somewhat severe diarrhoea. She also had attacks of epistaxis both in the early days and later in her illness. After the fourth day signs of pneumonia developed at the angle of the right scapula; there was little cough, no sputum, and no dyspnoea. This condition persisted until October 19th, when the temperature began to fall. By October 21st the temperature was normal and the patient felt pretty well. The signs of consolidation were quite marked in the region mentioned, and there were coarse crepitations. The temperature rose to 100° on the following evening, but came down in a few hours, and remained normal throughout her convalescence. The signs at the angle of the right scapula remained practically unchanged until October 28th, when they suddenly disappeared in one night. Her friends noticed that, during the acute period of her illness, the patient showed slowness and thickness of speech, though this was quite foreign to her usual condition. During convalescence her speech became normal, but she was able to remember very little about her illness.

CASE II.

Towards evening on October 26th the second lady, aged 35, who had slept in the same bed as the first patient, and had nursed her during the first week of her illness, felt unwell and shivery. On the following morning she was very drowsy, and suffered acutely from occipital headache and photophobia; her temperature was 102°, pulse 110, respirations 30. On October 28th her temperature rose to 104°; the headache and photophobia were still severe, and the patient said she felt as if her hair was being pulled. There were no physical signs, no cough, sputum, or dyspnoea. There was no tenderness anywhere except in the occipital region. The bowels were acting normally, and, except for some abdominal distension, she had no gastro-intestinal symptoms. On October 29th the temperature rose to 104.5°, the pulse was 116, and the respirations 30; the patient had some epistaxis, but her condition was much the same, except that the drowsiness and photophobia were less marked.

In the meantime it had been discovered, in the course of a chance conversation with the convalescent patient, that the ladies had an aviary at their home, and that the first patient had nursed a sick budgerigar for some days immediately preceding her illness. These facts, coupled with the suggestive course of the illness, prompted communication with the Ministry of Health.

On October 30th the temperature rose to 105°, the pulse was 118, respirations 30; there was slight impairment of note and diminution of the breath sounds at the angle of the right scapula. These signs became more pronounced during that day. On October 31st the temperature remained at 105° (there had been no remissions), respirations were 32, and the pulse varied between 102 and 120. The signs in the chest had become marked; there was bronchial breathing, dullness in the area already mentioned, and rales all over. Cough was slight, and there was no dyspnoea. The patient vomited a little, and started menstruating prematurely. S.U.P. 36 was given on this day with no result. This patient also showed some slowness of cerebration, and "wandered" during the night, though, when she finally understood a question, she answered intelligently but in a slow, hesitant manner. On November 1st the temperature was 104.5°, pulse 110, respirations 38; her condition was much the same. On November 2nd the temperature was 100° in the morning, with pulse 96, respirations 32; in the evening it was up again to 104°. On November 3rd and 4th the patient was worse; she took no interest in her surroundings, and moaned and sighed loudly for long periods; the first patient had also moaned a great deal. Her temperature was swinging between 99° and 104°. At midnight (November 5th–6th) the patient became collapsed; but the pulse soon strengthened and the temperature, pulse, and respirations began to fall until at 6 a.m. they were normal. She felt much better, and chatted in her usual way. That evening, however, the temperature rose to 102°, the pulse and respirations quickened, and she vomited. On November 7th the temperature was swinging between 99° and 104.5°, while the vomiting continued. On November 8th the patient became cyanosed, complained a great deal of epigastric pain, and died at midday.

It seems likely that this lady was infected by the previous patient, with whom she was in close contact during the first week of the latter's illness. Still, the possibility that she also came into contact with a sick bird before leaving home on October 10th cannot be entirely disproved; though, as she left home on October 10th and did not begin to be ill until October 26th, the incubation period was sixteen or more days. While this is not unknown, it is less usual than one of eight to fourteen days, a period coinciding with the time of her contact with an acutely ill patient.

CASE III

During the night of November 19th–20th, eleven days after the previous patient's death, a trained nurse, aged 63, who had been in attendance on both these cases, felt unwell. On November 20th she had epistaxis, and complained of frontal headache and vomiting. The pulse was 80, temperature 99.5°. On November 21st she was removed to hospital. This patient was undoubtedly infected by the patients she had been nursing; at no time had she been in contact with sick birds. During the first day after her admission into hospital there were no physical signs in the chest, but she vomited and was constipated; her temperature was 104° F., pulse 92,

respirations 30. On November 23rd there was dullness over the left lower lobe, with rales over the right side. The sputum was scanty and rusty. She complained a good deal of frontal headache, and had difficulty in swallowing. After November 24th she began to have incontinence of urine and faeces, which continued until her death. On November 26th there appeared to be paralysis of the left side of the body and the right side of the face, but this passed off in a couple of days. Gradually, however, nervous symptoms became more marked, together with abdominal tumescence, drowsiness, and symptoms generally reminiscent of typhoid fever. In fact, during the last five days of her life, the patient was in a typhoid state, more or less unconscious, and with a subnormal temperature. She died on the morning of December 3rd.

Two other nurses in attendance on the first two cases remained well, and there were no other cases in the home of the original patients.

SUMMARY

The sequence of events in these cases was as follows:

1. At the end of September or the beginning of October, 1930, patient No. 1 nursed a sick budgerigar.
2. October 11th, patient No. 1 fell ill when away from home on a visit. She eventually recovered, but as late as January 15th, 1931, was reported still to be suffering from insomnia, lack of energy, and occasional depression.
3. October 26th, patient No. 2 fell ill. She had nursed patient No. 1, had shared her bed, and was probably infected by her.
4. November 8th, patient No. 2 died.
5. November 19th, patient No. 3 fell ill. She was a hospital nurse in attendance on the previous patients from October 23rd, and was infected by them.
6. December 3rd, patient No. 3 died.

The source of infection of the budgerigar was not definitely traced. A number of other birds, budgerigars, foreign finches, and a blue and white canary, had died in the aviary from an unknown cause during September and the beginning of October, and the dealer who had supplied the birds admitted to deaths among the birds in his shop. Later on this dealer was found to have been importing budgerigars from the Continent, but he maintained that the birds he had sold to these ladies were home-bred.

SUMMARY OF NECROPSY (DECEMBER 4TH, 1930)

BY

DOROTHY S. RUSSELL, M.D.Lond.

RESEARCH ASSISTANT, PATHOLOGICAL INSTITUTE, LONDON HOSPITAL

Haemorrhagic broncho-pneumonia of lower lobe and of lower third of upper lobe of left lung. Early broncho-pneumonia of lower lobe of right lung. Congestion and emphysema of lungs. Anthracosis, engorgement, slight subacute inflammation and sinus catarrh of bronchial lymph glands. Acute and subacute inflammation without enlargement of spleen. A few streaks of submucous haemorrhage in caecum close to ileo-caecal valve. Slight injection of mucosa throughout intestinal tract. Slight fatty degeneration of myocardium. Considerable ischaemic atrophy of kidneys. Albuminous degeneration of tubular epithelium in kidneys; fatty degeneration of a few groups of second convoluted tubules. Severe degeneration of hypertrophied media and intima in large and small arteries. Ante-mortem thrombus adherent to ulcerated intima of anterior wall of very atheromatous abdominal aorta 3 cm. above bifurcation. Focal microscopic areas of bone formation in atheromatous and calcified intima beneath thrombus. Foramen ovale closed. Cardio-vascular hypertrophy. Focal ischaemic fibrosis of myocardium. Very severe atheroma of coronary arteries. Almost complete obliteration of right coronary artery by calcareous atheroma 1 cm. from its origin. Small area of softening and gliosis in right pulvinar. Area of gliosis and infiltration with pigment granule cells in ventral border of optic thalamus. A few petechial haemorrhages in basal ganglia. Congestion of brain. Central congestion of lobules of liver. Slight back pressure congestion of kidneys and spleen. Pitting oedema of left leg. Ante-mortem thrombosis of left femoral vein at brim of pelvis. Slight fatty infiltration of parenchyma and conspicuous fatty infiltration of Kupffer cells in liver. Fine granules of lipochrome in centres of lobules of liver and in myocardium. Brown atrophy of thyroid gland. Fibrous peritoneal adhesions between omentum and loops of small intestine obliterating pouch of Douglas. Slight focal chronic perisplenitis. Slight dilatation and injection of pelvis of right kidney. Aberrant branch of right renal artery entering lower pole of right kidney. Pancreas and suprarenal bodies normal. No macroscopic abnormality in muscles of abdominal wall. No enlargement of Peyer's patches or of solitary follicles.

MACROSCOPIC APPEARANCES

Lungs.—There was considerable injection of the trachea and bronchi. The pleural sacs contained no free fluid. Both visceral and parietal layers of the pleura were uniformly smooth and glistening. The lungs appeared small and congested. The upper lobes were conspicuously emphysematous, while the lower lobes felt boggy and slightly crepitant. The lower lobe of the left lung was heavier and fuller than the right, and felt unevenly nodular. On section the right lung appeared very congested. The upper and middle lobes were emphysematous. In the lower lobe there were numerous small, irregular, apparently peribronchial, areas of haemorrhage; there was no evidence of bronchitis or of consolidation; a little blood-stained frothy fluid exuded from the cut surface on pressure, and the tissue was aerated and floated in water. The left lung, on section, appeared different. With the exception of the upper two-thirds of the upper lobe the lung looked less aerated. At the apex of the lower lobe was an area of rather firm, swollen, finely granular, dusky, pinkish-grey consolidation. No fluid was expressed from this by gentle pressure. A similar area occupied the adjacent middle third of the upper lobe. In the remainder of the lower lobe there were numerous, sometimes confluent, finely granular areas of pinkish-grey peribronchial consolidation lying in a haemorrhagic ground. Dirty greyish-yellow slime exuded from the centres of these areas on pressure. The intervening lung tissue was deeply congested, and on pressure exuded a little fluid and very little air.

Bronchial Lymph Glands.—These glands were small and firm. The cut surfaces were flat and grey, and mottled with deposits of soot.

Spleen.—The spleen was small and moderately elastic. The capsule over the diaphragmatic surface showed a few irregular patches of fibrous thickening, between which were numerous pin-point glistening fibrous granulations. On section the cut surfaces were flat and firm. The trabeculae were easily seen, but the Malpighian bodies were indistinguishable. The pulp was a dull pink mottled with numerous small patches of deep red. There was no macroscopic evidence, therefore, of inflammation.

MICROSCOPICAL APPEARANCES

Lungs.—Blocks from the right lower lobe, the consolidated areas in the middle third of the left upper lobe and the apex of the left lower lobe, and from the broncho-pneumonic part of the left lower lobe, were taken for examination. In the right lower lobe some bronchioles were partly or completely filled with red corpuscles; most were filled with necrosed desquamated epithelium, ghosts of round cells, amorphous granular lumps, a few red corpuscles, and masses of cocci and bacilli. A few alveoli at the periphery of the section were emphysematous or partly collapsed; the remainder were filled with albuminous coagulum and a few red corpuscles, occasionally with many red corpuscles. They contained no fibrin, but everywhere were large numbers of Gram-positive cocci and Gram-positive and Gram-negative bacilli. Of these,

streptococci were the most abundant. In a few places were groups of Gram-negative bacilli of the influenza type. Immediately round some of the bronchioles the alveolar walls were necrosed and contained brown pigment. The pleura was unchanged. In the apex of the left lower lobe the bronchioles were either filled or lined with albuminous coagulum, desquamated epithelium, and red corpuscles, or a similar exudate containing neutrophil leucocytes. The walls of the bronchioles were very congested, and conspicuously infiltrated with large mononuclear cells, neutrophil leucocytes, and small lymphocytes. A similar infiltration was seen in the septa of the lung. The respiratory bronchioles occasionally contained coagulum and red corpuscles alone, but usually they contained numerous neutrophil leucocytes. Some of the adjacent alveoli were also crowded with neutrophil leucocytes, but mostly they showed coagulum, red corpuscles, a few neutrophil leucocytes, and desquamated epithelial cells, many of which were remarkably large. Other groups of alveoli were stuffed with red corpuscles, and were less distended. The distribution of these haemorrhagic areas appeared fortuitous: occasionally they encircled bronchioles or respiratory bronchioles, but in other instances they were of larger size and did not appear to have any special relationship to other structures. In these larger areas there were often poorly defined foci in which the alveolar walls were necrosed. Very little fibrin was present. The tissue was crowded with a great variety of Gram-positive and Gram-negative cocci and bacilli, among which streptococci were predominant. In one small area many minute bacilli resembling the influenza bacillus were present. The pleura was not affected.

In the lower part of the left lower lobe there was great distension of the bronchioles and respiratory bronchioles with neutrophil leucocytes, and sometimes with red corpuscles as well. The walls of the bronchioles were engorged and infiltrated as in the section from the apex already described. There was great purulent infiltration of the alveoli about the bronchioles, and around these was an outer zone in which the alveoli were slightly collapsed and occupied by albuminous exudate, red corpuscles, and occasionally a little fibrin. In other peripheral areas the alveoli contained less blood and more numerous neutrophil leucocytes and large epithelial cells. In some of the more haemorrhagic areas there was necrosis of the alveolar walls. Organisms were abundant as before. In the left upper lobe many of the bronchioles were empty; a few contained purulent exudate. Their walls were congested, but were less heavily infiltrated with cells than in the lower lobe. The respiratory bronchioles were distended with neutrophil leucocytes, and about these the alveoli were conspicuously infiltrated with neutrophil leucocytes, mononuclear leucocytes, desquamated epithelial cells of the remarkably large size seen in other sections, and a few red corpuscles. These pneumonic areas were sometimes confluent. In other places the alveoli were less distended and filled either with red corpuscles or with bubbly coagulum and occasionally a little fibrin. The septa of the lung were infiltrated with many neutrophil leucocytes and large lymphocytes. A great many organisms were present throughout the tissue as before. The pleura was unaffected.

Lymph Nodes.—The left bronchial lymph nodes were considerably engorged, and in a few places there were minute haemorrhages. Many large lymphocytes and plasma cells were present in the lymphadenoid tissue, but there was no emigration of leucocytes. There was an increase in the number of endothelial cells in the sinuses, and many had been desquamated. The glands contained considerable deposits of soot.

Spleen.—In a section of the spleen there was focal engorgement of the pulp. In the venous capillaries or sinuses there was an excess of neutrophil leucocytes and some large macrophages, a few of which contained red corpuscles. There was also an infiltration of the Malpighian bodies with neutrophil leucocytes. These were found round the central arteries and in the periphery, where they were accompanied by a few eosinophil leucocytes. In the pulp strands there were many plasma cells and large lymphocytes, a considerable number of neutrophil leucocytes, and a few macrophages. There was severe hyaline degeneration of the media and intima of the arterioles.

Discussion

The condition present in the lower lobe of the right lung appeared to be an early broncho-pneumonia. The necrosis associated with brown pigmentation of the contents of the bronchioles and of adjacent alveolar walls was probably due to acid digestion. The broncho-pneumonia may have been due to the inhalation of stomach contents before death, or it may have been an early stage of the condition seen in the apex of the left lower lobe complicated after death by acid digestion. In the left lung there was a broncho-pneumonia, characterized by purulent bronchiolitis of respiratory rather than of larger bronchioles, and a pneumonia which began with haemorrhage and marked albuminous exudate and later became leucocytic. There was extremely little fibrin formation and no thrombosis of vessels. The changes present in the apex of the lower lobe appeared to represent a stage earlier than those seen in the lower part of the left lower lobe and in the upper lobe. The pneumonia differed from an ordinary broncho-pneumonia in the absence of any marked degree of collapse, in the great abundance of albuminous and haemorrhagic exudate, and in the predilection of the inflammation for the respiratory bronchioles. It differed from a pneumonia in the concentration of the inflammatory reaction about the respiratory bronchioles. The presence of such large numbers of bacteria in all the sections could be explained by the lapse of over twenty-four hours between the time of death and the necropsy without storage of the body in a cold chamber; and also, perhaps, by the inhalation of stomach contents immediately before death. The great variety of bacteria found in the tissues made the task of identifying the pathogenic organism a hopeless one.

There was only a slight subacute inflammation of the bronchial lymph glands. The absence of enlargement of the spleen suggested that the acute inflammation found on microscopical examination was early and therefore a terminal event. The inflammation was probably due to a bacterial invasion of the lungs in the later stages of the illness. The septicaemia, therefore, was probably a late event. The only evidence of toxaemia was the presence of a little fatty degeneration of the myocardium, and albuminous and slight fatty degeneration of the kidneys. There was therefore little evidence of toxaemia.

A contributory cause of death may be found in the condition of the cardio-vascular system. Necropsy revealed extreme degeneration of the arteries and hypertrophy of the heart. In addition, there was almost complete occlusion of the right coronary artery by atheroma. Microscopically there was hypertrophy of the myocardium and of the muscular arteries, associated with very severe degeneration of both media and intima. In the abdominal aorta a section of the wall taken through a mass of adherent ante-mortem thrombus showed foci of bone formation in the degenerated intima. Further, the arterial change was correlated with ischaemic fibrosis of the myocardium and kidneys, and with microscopic patches of softening, gliosis, and rusty pigmentation in the basal ganglia. A moderate degree of terminal heart failure was indicated by the central congestion of the hepatic lobules, and slight congestion of spleen and kidneys, and perhaps by the few recent petechial haemorrhages in the brain. Ring-haemorrhages, evidently of toxic origin, have been observed in this laboratory in two brains from cases of *psittacosis* (Sturdee and Scott, 1930). The haemorrhages in the case under discussion were exceedingly scanty, were not ring-haemorrhages, and were associated with evidence of a few old haemorrhages. It is probable that they were due to the chronic vascular

degeneration, and not to an acute toxic change. The slight degree of fatty degeneration of the myocardium has already been quoted as evidence of toxaemia. It might, however, be argued that the degeneration was the sequel and not the precursor of the heart failure. The short duration of the heart failure, as estimated by the microscopical as well as the macroscopical changes in the organs, does not support such an argument. The thrombosis of the left femoral vein may either have been secondary to the heart failure or it may have been caused by the action of the psittacosis virus. Some support for the latter view lies in the finding of extensive pulmonary thrombosis by Turnbull (1930) in the first case of this disease reported from the London Hospital.

The conclusion drawn from the examination as a whole is that death was caused by a haemorrhagic broncho-pneumonia, acting upon a subject in whom the cardio-vascular system was already greatly impaired by degeneration.

The inflammation of the lung resembled that described in the first case of psittacosis examined in this hospital in the abundance of albuminous and haemorrhagic exudate and the presence of conspicuously large desquamated epithelial cells; but it differed in being a broncho-pneumonia rather than a pneumonia, in the almost complete absence of fibrinous exudate, in the absence of capillary and arterial thrombosis, and in the presence of bacteria in great number and of great variety. It was also complicated by acid digestion.

In impression preparations made from the spleen and stained by Giemsa the elementary virus bodies described by Levinthal, Lillie, and Coles were found.

NOTE ON THE BACTERIOLOGICAL FINDINGS IN THE ABOVE OUTBREAK OF PSITTACOSIS

BY

S. P. BEDSON, M.D., M.Sc.Dunelm.

SENIOR FREEDOM RESEARCH FELLOW

(From the Hale and Dunn Clinical Laboratories, London Hospital)

The material received for examination consisted of: (1) blood from patient No. 2; (2) a budgerigar (*Melopsittacus undulatus*) belonging to patients Nos. 1 and 2; and (3) organs obtained post mortem from patient No. 3.

Blood of Patient No. 2.—This was collected in an equal amount of 2 per cent. citrate on November 3rd, 1930, the seventh day of disease. It was received in the laboratory November 5th, and proved to be free from cultivable bacteria. Two mice, M. 235 and M. 236, were inoculated with this citrated blood, each animal receiving 0.5 c.cm. subcutaneously and 0.5 c.cm. intraperitoneally. One mouse, M. 236, died on the thirty-fifth day after inoculation, the other was killed when very ill on the thirty-sixth day. The post-mortem findings were in keeping with the death having been due to the virus of psittacosis. The spleen of Mouse 236 was suspended in 5 c.cm. tyrode and proved to be free from cultivable bacteria. Two mice, M. 255 and M. 256, inoculated intraperitoneally with 0.5 c.cm. of this suspension on December 11th, are still alive and well, February 23rd, 1931.

The Budgerigar B. 157.—This bird, belonging to patients Nos. 1 and 2, and nursed by patient No. 1 before her own illness, had been suffering from diarrhoea, and though it was in fair condition when seen by Dr. Sturdee of the Ministry of Health, November 3rd, he decided to have it killed and examined for the presence of psittacosis virus. Post-mortem examination of the bird showed injection of the intestines, a chamois-leather liver (fatty change), and enlargement of the spleen. The lungs appeared normal. The spleen and a small portion of liver—0.25 gram in all—were suspended in 5 c.cm. N/50 phosphate *p*H 7.6. The suspension was [illegible] sterile, and two mice were inoculated with it. The results obtained in this primary transmission experiment and subsequent passages are given in Table I.

TABLE I

Passage	Material	Mouse	Result
Primary transmission	Suspension of spleen and liver of budgerigar in phosphate; unfiltered; culturally sterile	M.233	Killed, moribund, tenth day
		M.234	Killed, very ill, tenth day
1st passage	Spleen of M.233 suspended in 10 c.cm. tyrode; filtered Chamberland L1 bis	M.241	Died seventh day.
		M.242	Killed, moribund, seventh day
2nd passage	Spleen of M.242 suspended in 5 c.cm. tyrode; unfiltered; culturally sterile	M.249	Died fifth day
		M.250	Killed, moribund, fifth day
3rd passage	Spleen of M.250 suspended in 5 c.cm. tyrode; unfiltered; culturally sterile	M.257	Killed, moribund, third day
		M.258	Ditto
4th passage	Spleens of M.257 and M.258 suspended in 10 c.cm. tyrode; unfiltered; culturally sterile	M.261	—
		M.262	Killed, very ill, fourth day
5th passage	Spleen of M.252 suspended in [illegible] culturally sterile	M.275	Killed, very ill, fourth day
		M.276	Ditto
6th passage	Spleens of M.275 and M.276 suspended in 10 c.cm. saline; unfiltered	M.281	Killed, very ill, fourth day
		M.282	Died fourth day
7th passage	5 [illegible]	M.287	Ill, second day, still under observation
		M.288	Ditto

Post-mortem Material from the Nurse (Patient No. 3).—This consisted of lung, liver, and spleen obtained at the post-mortem examination carried out by Dr. Dorothy Russell. A 5 per cent. suspension in tyrode made from the pooled organs gave a copious growth of a variety of organisms accounted for by the presence of numerous secondary invaders in the lung. This suspension was filtered through a Chamberland L1 bis candle, and two mice, M. 253 and M. 254, were inoculated with the filtrate, each receiving 1 c.cm. intraperitoneally. Both mice became ill ten days after inoculation. One, M. 254, died on the twentieth day, the other recovered. The spleen of M. 254 was suspended in 5 c.cm. N/50 phosphate *p*H 7.6, and proved to be free from cultivable bacteria. With this suspension further mice were inoculated, with a fatal result, and the strain has now been carried to the tenth generation in mice. This strain rapidly increased in virulence, and from the fifth passage onwards killed mice in two days. This is a point of some interest, for the great majority of human strains of psittacosis virus never attain any high degree of virulence and are difficult to maintain.

Identification of the Strains of Virus by the Neutralization Test.—The death of the two mice inoculated with the blood of patient No. 2 was in all probability due to psittacosis virus, but positive passage was not obtained; so this point remains unsettled. The two strains of virus, B. 157 and "Bangor" obtained from the budgerigar and the organs of the nurse (patient No. 3), were almost certainly psittacosis virus; but in order to settle this point beyond dispute the effect of neutralization with a specific serum was determined. The serum employed was one produced in mice, M. 176, M. 177, and M. 178, with a strain of virus "G.B." isolated from budgerigars. Previous work (Bedson and Western, 1930) had shown that this serum neutralized not only the homologous strain, but a strain isolated from a parrot and one from a Java sparrow as well. Mixtures of serum and virus (spleen suspension in saline) were made in which the final concentration of serum was 1 in 100, and the concentrations of virus 1 in 1,000 and 1 in 10,000. These mixtures were allowed to stand at room temperature and then inoculated intradermally in the guinea-pig in a dose of 0.2 c.cm. At the same time titrations of the two viruses were made in the same animal. The results of this experiment are given in Table II. The signs denote the degree of reaction in the guinea-pig's skin.

The strain "Bangor" is obviously the stronger, and probably the end point was not reached, but the strain B. 157 would certainly have gone no further than the 1 in 10,000 dilution. The serum therefore neutralizes approximately 100 m.l.d. of each strain of virus, a finding in

keeping with previous titrations of this serum with other strains of psittacosis virus (Bedson and Western, 1930).[1] Thus proof is forthcoming that the two strains B. 157 and "Bangor" are immunologically identical, and that they are strains of psittacosis virus.

TABLE II

Virus	Treatment	Dilutions of Virus		
		1 in 100	1 in 1,000	1 in 10,000
B 157 ..	Virus in saline (titration)	+	±	∓
	Virus with immune serum M.176, M.177, and M.178	−	−	
Bangor	Virus in saline (titration)	++	+	±
	Virus with immune serum M.176, M 177, and M.178	∓	−	−

CONCLUSIONS

Certain points arise out of the consideration of these cases. First, psittacosis is still liable to occur in this country, and should be borne in mind when one or more patients in a household are found to be suffering from an influenzal type of illness, with early signs in the lungs and perhaps some typhoid-like symptoms, such as epistaxis, abdominal distension, vomiting, constipation, or diarrhoea. Especially should such a diagnosis suggest itself if influenza is not prevalent in the surrounding neighbourhood at the time. Secondly, parrots are not the only birds which cause psittacosis in man. In the report of the Ministry of Health,[2] lovebirds, thrushes, and canaries, among other birds, are stated to have been the cause of human illness. It is apparently not certain how many types of birds suffer from diseases communicable to man, so the fact that a patient keeps birds should probably always arouse suspicion in doubtful cases of human illness. Certainly all bird keepers should take care always to wash their hands after attending to the birds, and especially before taking food. Thirdly, an unusual factor in the cases described in this article is that three generations of human psittacosis followed from the original sick budgerigar. Cosman, quoted in the Ministry's report, mentions a woman who caught psittacosis from a patient she nursed and afterwards infected her own child, but such a sequence is sufficiently unusual to be worth noting. Fourthly, the infection of a trained nurse in the course of her ordinary duties shows the care required in dealing with psittacosis, and incidentally, therefore, the necessity of early diagnosis of the disease. The nurses attending on these patients were warned to treat them like cases of typhoid, and this is probably all that can be done. So far as is known, this is the first instance in this country of the infection of a hospital nurse with psittacosis by her patient, and, even so, two out of the three nurses in attendance escaped the disease.

A CASE OF CEREBELLAR ABSCESS

BY

COURTENAY YORKE, M.D., F.R.C.S.

AURIST AND LARYNGOLOGIST TO THE LIVERPOOL STANLEY HOSPITAL

Cerebellar abscess is not a very rare condition, and recovery occurs after operation in a small percentage of cases. It is thought, however, that the following case may be of sufficient interest to report, on account of its dramatic course, and also because of important considerations of treatment that it raises.

CLINICAL HISTORY

On January 8th, 1931, Dr. A. Moscrop Walker of Wallasey asked me to see, in consultation, a girl, E. M. T., aged 13, who had acute middle-ear suppuration, with involvement of the mastoid. I was informed that the ear infection had set in suddenly at a boarding school a fortnight previously, and that there had been no antecedent ear trouble. The mastoid symptoms were only of a few days' duration. On examination I found the left ear discharging. There was also tenderness and swelling over the mastoid and above the ear. The pulse rate was 120, and the temperature 99.4° F. The patient was moved to the Wallasey Cottage Hospital, and an operation was performed the same night.

The entire mastoid was in a condition of acute osteitis, and there were numerous small collections of pus scattered throughout the mastoid cells. There was also pus in the mastoid antrum. The mastoid was widely opened, a large rubber tube being used for drainage.

The patient was more comfortable after the operation, and for the first five days appeared to be progressing satisfactorily. It was observed, however, that she was rather apathetic and disinclined for food, but no special misgiving was felt on that account. On January 14th she vomited twice and became more lethargic, but there was no headache, and the temperature and pulse were normal. Later in the day she refused food, and during the night passed rapidly into a semi-comatose condition, with occasional meningeal cries. On the following day the coma deepened and she responded to questions in monosyllables only, and after long delay. She lay curled up on the right side. Incontinence was present. The eyes were half open, fixed, and staring. The pupils were unequal, and the right one was a little irregular in outline. The right eye was very slightly deviated downwards and outwards. There was no nystagmus and no papilloedema. The mouth was open and the tongue dry and furred. The temperature was 97.5°, and the pulse rate 76.

The case appeared to be one of brain abscess, but whether in the cerebrum or cerebellum it was impossible to say. Under ether anaesthesia the temporo-sphenoidal lobe was explored, without pus being found. The more difficult exploration of the cerebellum was then commenced, but before the dura mater of the posterior fossa was exposed, the condition of the patient became so alarming that the operation had to be rapidly terminated.

On January 16th the coma was deeper and the patient could not be roused. Lumbar puncture was performed, and 10 c.cm. of clear cerebro-spinal fluid was withdrawn under pressure. It was decided to make a further attempt to explore the cerebellum. A general anaesthetic being out of the question, 1/6 of a grain of morphine was given hypodermically, and the operation of the previous day was resumed as the patient lay in bed. An area of dura mater, the size of a sixpence, in front of the lateral sinus, was at length exposed. The dura was incised and a knife inserted into the cerebellum to a depth of one inch in different directions, but without result. A Record syringe with a stout needle was then tried, and at a depth of one and a half inches one drachm of pus was withdrawn. A small rubber tube, the width of a slate pencil, was used for draining the brain abscess. It was stitched to the skin to prevent displacement.

The withdrawal of pus was immediately followed by deeper breathing. The coma lifted slowly and consciousness was not fully restored for two days. Incontinence continued for nearly a week. When the patient was sufficiently conscious to co-operate in the eye tests, the changes observed were as follows: (1) nystagmus, on movement of the eyes to the left; (2) conjugate deviation of both eyes to the right, in the normal resting position; (3) diplopia, the right eye was inclined downwards and outwards; (4) the eyes had a fixed, staring appearance, spontaneous movements were very limited, and the patient was unable to move the eyes together in different directions and hold them there. She did not experience any

vertigo, and there was no homolateral weakness of the limbs or muscular inco-ordination.

On January 18th the use of the tube was discontinued, the discharge having ceased. It was thought that the tube might be obstructing the sinus, and the latter was kept open by fine forceps during the next two days. Between January 20th and 29th, apart from a quick pulse and a moderate pyrexia, there were all the indications of excellent progress. The eye changes disappeared except the nystagmus, incontinence ceased, and the appetite was fully restored. The mind was clear and animated. On January 31st a sudden relapse occurred, and the patient became rapidly comatose again. The tube was reinserted, but for several days she remained in a moribund condition, and could not be induced to swallow more than an occasional teaspoonful of water. Hiccup was a prominent symptom at this stage.

After these critical days had passed rapid improvement set in. The pulse and temperature remained normal and progress was uninterrupted. The tube drained freely and was left in for a fortnight, until it could no longer be inserted.

During the whole of this period the tube was taken out for cleaning twice daily. It remained, however, stitched to the skin all the time, so that there was no uncertainty in reintroducing it to the proper depth. The girl was able to get up on February 19th and returned home on February 25th. Since then she has made unremitting progress. The nystagmus disappeared in a week or two. Now, at the end of April, she is in vigorous health and entirely free from any ill effects of her serious illness.

CONCLUSIONS

The conclusions to be drawn from this case are:

1. That brain abscess may develop insidiously, and that the first intimation may be incipient coma.

2. That a hypodermic syringe may discover pus when other means fail.

3. That drainage should be continued as long as possible; for this purpose a very small tube may be adequate, the pus escaping alongside it rather than through it.

THE TECHNIQUE OF SURGICAL DIATHERMY

DESCRIBING A NEW ELECTRODE

BY

ALBERT EIDINOW, M.B., B.S.

HONORARY PHYSICIAN TO THE LONDON LIGHT AND ELECTRIC CLINIC, VICTORIA, S.W.

The electric current employed in diathermy treatment and for surgical operations is of the nature of a high-frequency current. D'Arsonval (1895) showed that an alternating electric current, making and breaking about 15 times per second, would produce clonic contraction of isolated muscle preparations when tested *in vitro*. When the frequency of the current was increased 20 to 30 times per second tonic spasm was observed. The severity of the muscular contraction was augmented as the frequency was increased up to 300 cycles per second. Beyond this optimum the response of such muscle preparations to electrical stimuli diminished, and at about 10,000 times per second muscular spasm ceased and heat was developed. Electric currents which oscillate at 10,000 times per second are known as high-frequency currents; they have an entirely separate physiological action on tissues, as they cause heating, in contrast to lower frequency currents, which cause muscular contraction.

HIGH-FREQUENCY CURRENTS IN DIATHERMY

High-frequency electrical currents which are employed in diathermy or for surgical operations are obtained by means of coils and condensers. The main alternating current supply of 100 to 250 volts, and frequency of 50 to 60 cycles per second, is connected to the primary coil of a transformer; by this means a high voltage alternating current is developed in the secondary coil, which is connected to a series of condensers storing up the electrical charge until the voltage is sufficiently high to cause discharge through a spark-gap. The condensers are immediately recharged, and the process is repeated. With modern diathermy apparatus these oscillations are continuously maintained. The oscillating high-frequency current is taken up by a resonance coil of low resistance, and a second circuit is connected to the patient, which, when properly applied, produces the effects of diathermy. In place of the spark-gap, thermionic valves, three-electrode valves, or grid valves may be employed; these give a smoother current, which is perfectly continuous, but have the disadvantage that they are fragile and costly; further, they cannot carry a very heavy load of current. By such methods it is possible to obtain a high-frequency current of 3,000,000 cycles per second. Currents of electricity travel at a constant speed of 300,000 kilometres per second, but the nature of the wave-length transmitted varies with the frequency. Thus, a wave-length of 300 metres corresponds to a frequency of 1,000,000 cycles per second. The nature of the vibration of an oscillating current may be similar to the motion of a vibrating violin string, or it may be a series of undulating waves of uniform magnitude. The former are called damped oscillations, and the latter undamped oscillations. The thermionic valve apparatus emits a continuous flow of undamped oscillations; the apparatus containing spark-gaps produces damped oscillations. Each type of high-frequency current, differing in wave-length, causes variable reactions when applied to living tissue. The biological action of high-frequency current depends upon: (1) the intensity or amperage; (2) the tension or voltage; (3) the frequency of wave-length; (4) the nature of the oscillations; (5) the size of the electrodes; and (6) the electrical conduction of the living tissue. The amperage, voltage, and frequency directly control the intensity and dissipation of electrical energy, and therefore regulate the quantity of energy in terms of electricity or heat. As the amperage is increased the voltage and frequency diminishes; and, as a result, a heavier diffused current is generated, which is suitable for coagulation of tissues, and has greater power of penetration.

SURGICAL DIATHERMY

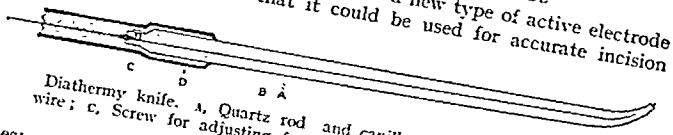
As a rule two electrodes are necessary for surgical diathermy. A large indifferent electrode is attached to a big area of the skin of the limbs or abdomen, and allows a wide path for the current to be generated to the body. This is discharged at the point of contact with the second active electrode. The size of the electrodes are directly proportional to the conduction of heat. Therefore a pin-point electrode will cause a discharge of electrical energy over a small area and result in rapid destruction of tissues by coagulation; whereas a larger plate electrode will have a generally diffused temperature effect over a wide area, which will not be sufficient to destroy tissue, but will only generate heat. The latter is the principle involved in therapeutic uses of diathermy. In order to obtain a maximum effect of deep penetration, a long wave-length current is applied by generating electricity at a high amperage, low voltage, and low frequency of damped oscillations. The maximum warmth the patient will tolerate is carried to the site of application by two large lead plates, copper foil or mesh, which are employed as the active electrodes.

Coagulation and Excision Technique

In surgical diathermy high-frequency currents are employed in two ways: (1) for the destruction of tissue by coagulation; and (2) for direct excision, similar to excision by a surgical knife. For coagulation, the active electrode is, as a rule, a small metal button or ball of varying shape and size, attached to an insulated handle and rubber-covered flex. The whole should be designed so that it can be completely sterilized. The extent and depth of coagulation is regulated by: (1) the intensity of the diathermy current; (2) the time the electrode is in contact with the tissues; and (3) the nature of the electrical conductivity of the tissues. For this purpose spark-gap diathermy apparatus is superior, as it permits a heavier load of current to be generated. This is desirable when coagulating large areas of diseased tissue. A current of relatively high amperage (1 to 20 amperes), low voltage and low frequency (under 1,000,000 cycles per second) is employed. Firm pressure should be applied, and the diseased tissue should be slowly coagulated. If too much current is employed, sparking, fulguration, and haemorrhage will result, which will rapidly cause a charred dry scab, as this is a poor conductor, it will inhibit the passage of further current; by consequence there will be only a superficial destruction of tissue, the diseased parts of which will remain within the depth of the lesion. In coagulation technique a "white reaction" should be obtained rather than a black eschar. After the coagulation operation is completed, it may at times be necessary to fulgurate the surface of a lesion, or the coagulated region may be completely excised by the cutting current and the excision technique. At first the active electrode should be firmly applied to the diseased tissue; the apparatus is then switched on with the indicator dial at the zero mark, and the current is gradually increased until "white coagulation" can be seen spreading around the margin of the electrode; the switch is then turned off and the electrode is moved, and a further area of diseased tissue is coagulated in a similar manner. If the active electrode is applied with too heavy a load of current passing through, only charring and sparking of the surface layers will result, and the deeper layers will not be heated. Similarly, sparking will occur if the active electrode is suddenly released before the apparatus is switched off. The depth of coagulation can be controlled by regulation of the intensity of the current, by the size of the active electrode, and by the time it is in contact with the tissues. Whenever it is practicable, coagulation should be continued until it can be seen that it has penetrated throughout the depth of the diseased tissue to the surface layer of the healthy tissue. Rapid coagulation, the use of small electrodes, or excessive current are to be avoided. The coagulation may be further controlled by the use of a thermo-couple embedded in a hollow needle, and in this way the temperature at any given region can be recorded by observation of the deflection of the needle of a sensitive galvanometer. Cutting tissues by means of the diathermy current involves a technique which is different from the methods of coagulation. A diathermy current of short wave-length, low amperage (100 to 200 milliamperes), higher voltage (4,000 to 8,000), and a frequency of 3,000,000 oscillations per second is usually generated. The active electrode is a fine needle or a wire loop. The object of such operations is to cut tissues cleanly with the minimum diffusion of coagulation beyond the limits of the incised area. In this way a bloodless incision is attempted, which, after suture, should heal by first intention. Many types of active cutting electrodes have been described. Many of them are too long and do not allow the depth of incision to be controlled. Others are too thick, and cause diffused coagulation.

AUTHOR'S CUTTING ELECTRODE

Recently I have designed a new type of active electrode (see Fig.) so that it could be used for accurate incision



Diathermy knife. A, Quartz rod and capillary bore; B, Molybdenum wire; C, Screw for adjusting free end; D, Rubber tubing.

and dissection of tissue with the same safety as the surgeon's scalpel.

This electrode consists of a molybdenum wire which projects 2 mm. beyond a quartz rod. This quartz rod is about 9 inches long and is tapered and bent at its end; a capillary hole is bored throughout its whole length, and the molybdenum wire is threaded through the fine hole and projects for 1 to 2 mm.; this can be regulated and adjusted by a clamping screw. The molybdenum wire is connected to some copper flex, which is covered by rubber tubing throughout its whole length, and is attached to the outer wall of the terminal half-inch of the quartz rod. In this way the electrode is completely and safely insulated, and can be readily sterilized by boiling. Since fused quartz can withstand high temperature, rapid cooling, and is a good insulator, there is no danger that this electrode will be damaged or crack. The electrode can be used repeatedly, as it is rustless and is not softened or damaged by high temperature or oxidation. The length of the active end of this electrode is roughly 2 mm., and it is surrounded by the quartz capillary bored rod and therefore is well insulated.

By this means it is possible to cut and dissect tissues carefully and to operate on vascular areas, avoiding the important large blood vessels and nerves. The depth of the incision can always be controlled with the same care as with the scalpel. Pressure on the electrode should be avoided, for the incision is made by the electrical discharge from the point of the active electrode.

Operative Technique

Skin and muscle are readily incised, but fat and hard scar tissue are more difficult to deal with, as they are poor conductors of electricity. A heavier current is necessary, and at times the dissection of a mass of fat will prove difficult and laborious. The electrode should be used with a rapid light stroking movement; for if it is left in contact with tissues for long, diffuse coagulation will result. Bleeding is rarely excessive, except from the larger blood vessels, which should be clamped in the usual way, and later sealed off by applying the point of the electrode to the pressure forceps and changing over from the cutting to the coagulating diathermy current. It is advisable to ligature larger blood vessels by the usual methods. The control of the diathermy current during operations needs skill and knowledge. The current should be slowly regulated to obtain the correct cutting effect so that the coagulation does not spread further than 0.3 mm. The intensity must be regulated from time to time during the whole operation to compensate for the changes in conductivity of the various tissues—that is, skin, fatty tissue, muscle, and scar tissue. Excessive discharge of current or incorrect frequency will cause sparking, and result in diffused coagulation. Operation by the diathermy current produces a sterile and almost bloodless incision; the lymphatics are sealed off and the danger of dissemination of malignant cells or bacteria is diminished. The heat caused by the high-frequency current counteracts the surgical shock following exposure of wide areas of tissues, which are quite warm after diathermy operations.

Indications for Operation

This method of operation has been employed for:

1. The excision of areas of disease of the tongue and palate.
2. The excision of malignant disease of the breast.
3. Excision of areas of necrosis and ulceration following malignant disease.
4. Radium and *x*-ray necrosis and ulceration.
5. Excision of tissue in vascular areas, in which it is difficult to control haemorrhage by other means (bladder and brain).

The cases which have been selected for diathermy were those in which surgical operation by other means would be difficult owing to the danger of haemorrhage or the inability to dissect successfully the adherent masses of scar tissue. The operation for excision of the breast by diathermy has invariably healed by first intention. At times it has been possible to excise a mass of adherent malignant glands, even when in close proximity to the axillary vessels. Foul and sloughing malignant ulcers have been excised, and the base has been coagulated, leaving clean granulating surfaces with consequent relief of pain and discomfort. It has been possible to heal cases of *x*-ray ulcerations and radium burns in the same way, such treatment giving immediate relief of the pain associated with these lesions. After diathermy operations a solution of flavine in liquid paraffin applied once every day is a suitable dressing. On the seventh to tenth day after operation a slough separates, leaving a clean granulating surface. Healing at this stage may be accelerated by means of ultra-violet irradiation. In successful cases wide areas may be excised or destroyed by the diathermy current, and will finally heal completely without the necessity of skin graft. Diathermy operations of the tongue, tonsil, and palate cause more severe reaction; oedema is marked, and secondary haemorrhage may occur at the stage of separation of the slough. It is more difficult to obtain healing by first intention. I have attempted to dissect tonsils by means of the cutting diathermy current with the help of Mr. E. Steeler. In all, twenty cases were done. We obtained good results in eighteen cases, but in two cases secondary haemorrhage occurred nine days after operation. The destruction of enlarged tonsils by the technique of coagulation has given favourable results in adult patients. Surgical diathermy is a very useful agent for the removal and destruction of naevi, moles, and warts. The operation is rapid and bloodless, it can be performed without anaesthesia, and results in a successful healing with no unpleasant disfigurement or scar.

I am indebted to Mr. Stanford Cade and Mr. Douglas Harmer for their valuable help in giving me the opportunity to assist them at operations.

MEDICAL, SURGICAL, OBSTETRICAL

SUICIDAL CUT THROAT: RECOVERY

The following case of a suicidal cut throat recovering, after very severe injuries, seems of sufficient interest to publish.

On January 19th, 1931, in answer to an urgent call to the receiving ward at the West Middlesex Hospital, I found a well-nourished man, aged 30, sitting fully dressed, with a loose scarf bandage draped around his neck, and his head slightly flexed and rotated to the left. On examination I found the patient almost aphonic, with a circular cut in the neck 5 inches in length, extending from about 1 inch to the right of the mid-line, to 4 inches to the left of the mid-line, at the level of the upper border of the thyroid cartilage. There was comparatively little bleeding, although the cut extended through all soft tissues, including the infrahyoid group of muscles, the thyrohyoid membrane, the tip of the epiglottis, and the lateral walls of the pharynx, back to the vertebrae. There was abundant discharge of mucus. Temperature 97°, pulse 130, respirations 24.

I learned that this was a suicidal cut, inflicted with an ordinary razor in a moment of financial anxiety. I ordered a hypodermic injection of morphine 1/4 grain to be given statim. After consultation with the medical superintendent, Dr. J. B. Cook, we decided against any attempt at surgical repair. Warm saline dressings were applied to the neck, and rectal glucose and coffee salines were given six-hourly: also a hypodermic injection of adrenaline co. 1 in 1,000, with atrop. sulph. 1/200 grain, and strychnine hydrochlor. 1/100 grain.

On January 22nd the patient started taking sips of water and diluted milk by mouth; the rectal salines were gradually discontinued, and by the 25th he was taking an ordinary fluid diet and the neck wound was healing up rapidly. On February 17th the patient started getting up; and, except for an attack of influenza which developed on the 22nd, he made an uninterrupted recovery. He was bright, and quite normal mentally, during the whole of his stay in hospital, and was discharged cured on March 19th.

I have to thank the medical superintendent for allowing me to publish these notes.

MARJORY W. WARREN, M.R.C.S., L.R.C.P.,
Assistant Medical Officer, West Middlesex Hospital, Isleworth.

TREATMENT OF PERNICIOUS ANAEMIA

The following brief history of a case of pernicious anaemia, which I have had under my observation for nearly three years, and now appears to be cured, may be of some interest from the point of view of treatment.

I first saw the patient, a man aged 54, on July 24th, 1928. He was then complaining of shortness of breath and weakness. His heart was dilated, auscultation revealing a mitral systolic murmur, and there was some oedema of both legs; he was very pale, and at first I thought of aortic disease. He gave a history of not feeling well for a year, and of having weakness in the right arm and leg. The knee-jerk on the right side was very feeble, and the hand-grip on the same side was weak. Examination of a blood film showed a typical picture of pernicious anaemia, with the exception that there were very few nucleated red cells. I was at the time unable to make a blood count, but the haemoglobin was 60 per cent. There were some petechiae scattered over the chest and back.

I prescribed half a pound of raw liver daily, and 5 minims of liquor arsenicalis and 10 grains of ferri et ammon. cit. to be taken three times a day. The patient responded fairly quickly, so that on September 11th the haemoglobin was 80 per cent., and on October 6th 90 per cent. The dose of liquor arsenicalis had been increased to 8 minims. He ceased attending in the early part of October.

He again appeared in June, 1929. His condition had deteriorated, and his haemoglobin was only 60 per cent. He had acquired a distaste for raw liver, and had not been taking it very regularly, I think. I put him on liver extract, in full doses, and the arsenic mixture as before. On July 20th a blood count showed 1,800,000 red cells per c.mm., and the haemoglobin was 75 per cent. Instead of the arsenic mixture dilute hydrochloric acid was given in 30-minim doses three times a day, with tincture of nux vomica and gentian. On October 17th the red cell count was 1,250,000 and the haemoglobin 60 per cent. On October 21st the haemoglobin had gone up to 80 per cent. He was now taking raw liver as much as possible, and the extract only at intervals.

He did not attend again until April 19th, 1930. His condition was then so grave that I suggested treatment in a hospital, with a view to transfusion of blood, but he would not agree to this. He was extremely weak and dyspnoeic. His right leg had again become weak. A blood count showed that the red cells were down to 950,000 per c.mm., and the haemoglobin was 50 per cent. Throughout his illness he had an extremely high colour index. His appetite was very poor, and he found it impossible to take raw liver on account of the nausea and loathing it produced. He had been receiving the equivalent of 6 ounces of liver, as liver extract, daily. I now gave him 1 drachm of glycerin of pepsin, with 30 minims of dilute hydrochloric acid (later increased to 40 minims), and 10 minims of tincture of nux vomica, three

times a day after meals. His nausea quickly disappeared, and he was then able to take the juice of 8 ounces of raw liver daily. The liver was cut up into very small pieces and all the juice expressed. From this moment he never looked backwards.

On April 26th the red cells were 1,465,650 per c.mm., and the haemoglobin was 60 per cent. On May 3rd the red cells were 1,856,250, and the haemoglobin was 70 per cent. On May 20th the red cells were 3,416,000, and the haemoglobin was 70 per cent. During this period there was a considerable increase of nucleated red cells. On July 12th the red cells had increased to 4,166,250, and haemoglobin to 90 per cent., on July 19th the red cells numbered 4,875,000, and on August 1st the red cells numbered 5,373,250, and haemoglobin was 100 per cent. He is now taking 4 ounces of raw liver juice daily as a prophylactic.

The interesting point is that, his irregular attendance apart, the patient's improvement was slow until, in addition to his raw liver, he took glycerin of pepsin and acid mixture. He improved certainly with arsenic, and to a lesser degree with dilute hydrochloric acid, but it was not until I gave him the glycerin of pepsin that a really striking improvement occurred. A rise in the red cell count from 950,000 to 5,373,250 in less than four months is certainly remarkable. The grip of his right hand is now quite strong, and there is only slight weakness in his right leg. In fact, the man is hardly recognizable as the wreck I saw a year ago.

In future I shall certainly put any more patients with pernicious anaemia on to glycerin of pepsin or some other form of stomach extract straight away, in addition to the raw liver juice. Liver extract did not seem in this case to be nearly as effective as the fresh raw product.

London, S.W. H. C. KEATES, M.D. B.S.Lond.,
Lieutenant-Colonel I.M.S. (ret.).

Reports of Societies

THE OBSTETRICAL PROBLEM OF CONTRACTED PELVIS

At the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on May 15th, under the presidency of Sir EWEN MACLEAN, a discussion was held on the relative value of the induction of premature labour, test labour, and Caesarean section in minor degrees of contracted pelvis.

Mr R. ALAN BREWS said that the practice at the London Hospital in all cases of contracted pelvis was either elective Caesarean section or test labour. In the three years covered by his statistics induced premature labour for contracted pelvis had never been done. The cases treated were those in which there was true clinical disproportion—a head which could not be engaged and which would not go into the pelvis without holding. He had divided them into two groups—namely, those in which the diagonal conjugate was above 4¼ inches, and those in which it was between 3¾ and 4¼ inches. The total number of deliveries in the hospital had been 5,284 in three years, and the number of cases in which test labour or Caesarean section had been employed in the treatment of minor degrees of contracted pelvis was only 45. The number of spontaneous deliveries had been 29, of assisted deliveries 3, and of Caesarean section following test labour 13. No maternal mortality had resulted, and morbidity had occurred in only two cases. The foetal and neo-natal mortality had been 4.8 per cent. The cases treated by Caesarean section had been attended by no foetal mortality, as well as by no maternal mortality or morbidity. The advantages of test labour were that the uterus and the pelvis were given a chance of showing what they could do, and that all the infants were full term. Uterine inertia, occipito-posterior positions, and early rupture of the membranes were difficulties that had to be dealt with. Pelvic measurements were of great value when dealing with test labour; in the vast majority of cases with large pelvic measurements the child came through perfectly easily, and there was a normal puerperium.

Mr. G. F. GIBBERD considered that a satisfactory definition of moderately contracted pelvis was impossible. The standard adopted at Guy's was "the degree of disproportion where intervention seems necessary." The total deliveries in three years had been 5,045, and 186 patients had been treated for contracted pelvis; of these, 133 had been unselected, and in 53 some difficulty had been anticipated before admission. Inductions had been performed in 83 cases, trial labour followed by Caesarean section in 42, and forceps delivery in 61. His figures did not take into account the cases in which trial labour ended in spontaneous delivery. Although forceps delivery figured largely in the results, his hospital did not advocate it as a method of treatment. It had been used in the inevitable rubbish heap of cases in which other treatment might have been tried had there been earlier opportunity; and also in cases in which induction of premature labour had wrongly been considered unnecessary. The infant mortality attending forceps delivery (18 per cent.) was therefore not so much a condemnation of forceps delivery as an indication of how far other methods fell short of the ideal. In his view there was room both for trial labour and for induction of premature labour. By the use of both methods, and by forceps when some degree of disproportion held up the second stage of labour, he felt that better results were forthcoming than by rigid adherence to one method in all cases.

Dr. J. W. A. HUNTER brought forward figures for St. Mary's Hospitals, Manchester. He had made a careful examination of the records of 850 cases treated during the past five years for a minor degree of contraction, choosing only those cases which had been delivered in hospital after attending the ante-natal clinic. Figures for primigravidae and multiparae were presented separately. He said that a large proportion of the cases had been treated by induction—77 per cent. in the one group and 54 per cent. in the other. The average time of induction of labour had been the thirty-eighth week. Medicinal induction—namely, castor oil, quinine, and pituitrin, or in a few cases castor oil and quinine only, or ovarian extract only—had been successful in 82 per cent. of cases. The resulting delivery in 68 per cent. of inductions of premature labour had been by natural forces. There had been one maternal death out of 277 inductions of premature labour in the primiparae, and none out of 270 inductions among the multiparae. The cases delivered by Caesarean section in the first group had numbered 37, with no maternal deaths, and in the second group 164, with 4 deaths. The high proportion of Caesarean sections among the multiparae was because many of the women had been known to have had stillbirths previously. As to trial labour, there had been 23 cases in the first group, and 41 in the second. Induction with delivery by Caesarean section had been practised in 16 cases, with 2 maternal deaths; and trial labour with delivery by Caesarean section in 32 cases, also with 2 maternal deaths. One significant point was the high foetal or infant mortality resulting from trial labour (14.3 per cent. in the primiparae, and 21.9 per cent. in the multiparae). He put forward a plea for the method of induction of premature labour. Out of the 275 cases in which induction of premature labour had been practised in multiparae, just over half the previous confinements of these women had resulted in stillbirths, or the infants had died shortly after delivery. The way in which infant welfare centres now looked after premature children, practically not allowing them to die, could be set against the disadvantage of the method from

the point of view of the infant. Caesarean section showed the highest maternal mortality and the lowest foetal mortality, though the latter was not appreciably lower than that in the induction of premature labour. He protested against the ever-increasing practice of Caesarean section, which was insidiously assuming such proportions as to threaten to become a national menace. In the series of cases from his own hospitals there had been eight deaths following Caesarean section out of 249 cases in which it had been practised for contracted pelvis (diagonal conjugate, 4 to 4½ inches). Of the eight deaths, three had been due to peritonitis, and the others to tuberculous pneumonia, paralytic ileus, post-partum haemorrhage, faecal fistula, and pulmonary embolism.

Dr. A. MORRIS-JONES sent a communication from Queen Charlotte's Hospital, which was read. Out of 10,646 deliveries in five years, 1,285 were for contracted pelvis, of which 814 were delivered by induction, 327 by forceps, and 144 by Caesarean section. All the inductions took place between the thirty-sixth and thirty-ninth weeks; 475 cases were successfully induced by mechanical contrivances, and 339 by drugs. Of the 144 cases in which Caesarean section was done for disproportion, 7 of the women had previously undergone induction in the nature of trial labour. Two of the Caesarean section patients died, of septicaemia in the one case, and post-partum haemorrhage in the other; and 38 cases showed some degree of morbidity. The foetal mortality rate following Caesarean section was 4.1 per cent. The number of maternal deaths following induction was 7, and 3 followed forceps delivery; 79 cases in the former category and 71 in the latter showed morbidity. The foetal mortality was 8.09 per cent. in the case of straightforward induction, and 30 per cent. in the case of induction with forceps. He considered the figures justified the rather high proportion of cases in which induction was decided upon.

Dr. GLADYS HILL, for the Royal Free Hospital, said that the standard of contraction there laid down was that the head could just enter the pelvis at the thirty-eighth week. Out of 46 inductions in primiparae and 15 in multiparae, 48 had ended in spontaneous delivery, and 13 had forceps. There had been no maternal mortality; the maternal morbidity had been 9.8 per cent., and the infant mortality 14.7 per cent. With the 17 primiparae and 5 multiparae submitted to Caesarean section after test labour there had been no maternal deaths; the maternal morbidity had been 22.7 per cent., and the infant mortality 4.5 per cent. Taking the whole of the cases, the stillbirth rate (9.81 per cent.) was about three times the foetal death rate for the whole of the deliveries at the hospital (9,468) during the period covered. The average weight of the infant in the cases induced had been about one pound less than the average weight in the cases in which Caesarean section had been performed. From the maternal point of view, the chief favourable factor in Caesarean section was the avoidance of a labour definitely prolonged above the average; but against this was the higher morbidity rate, the risk attending an abdominal operation, and the presence of a scar in the uterus, though such a scar had been found not to preclude subsequent delivery by the natural route. A further advantage was that the infants were all alive, all at term, and with no birth injuries. She added that it was a matter of observation that as one became more experienced in ante-natal work the proportion of cases in which intervention was regarded as necessary was diminished.

Dr. J. GARDINER WIGLEY gave figures for St. Thomas's. Out of a total of 2,572 deliveries the cases in which a moderate degree of contracted pelvis called for treatment numbered 137. The maternal mortality rate had been 7 per cent., the morbidity rate 13.1 per cent., and the infant mortality rate 10.9 per cent. Most of the cases (92) had been treated by induction, and 23 by induction and forceps.

Dr. A. J. WRIGLEY, for the General Lying-in Hospital, York Road, said that the total number of deliveries from 1925 to 1930 was 6,012, of which 184 had a slight degree of contraction. No emergency cases were included in this series. Of these cases 47 had spontaneous delivery, 17 had forceps, 103 had induction (with spontaneous delivery in 94, and with forceps in 9), and there had been 17 Caesarean sections. Only one maternal death had occurred in the whole series; this was a woman in her fourth pregnancy, who had been induced, with spontaneous delivery. The morbidity had been 4.3 per cent., and the total infant mortality 10.8 per cent.

Sir EWEN MACLEAN briefly reviewed the reports brought forward by the hospitals, and expressed a wish that some of the speakers had illustrated a little their difficulties with regard to the measurement of the diagonal conjugate. Presumably the difficulties were not the same in all cases, but confidence in perimetry generally was to be attained only after considerable experience and after testing one's forecasts by the after-history of the cases. He thought there would be general response to the protest of one speaker against the abuse of Caesarean section. Apparently at Guy's that operation was performed only after trial labour.

Mr. ALECK W. BOURNE said that the first thing that struck him in the discussion was the uncertainty as to the type of pelvis about which they were talking. He felt that a number of cases of induction, supposedly for minor degrees of pelvic contraction, were really not done on account of such contraction. They were not troubled in conducting labour nearly so much by a small degree of contracted pelvis as by the unflexed head. Therefore, although he came from a hospital which had had opprobrium thrown upon it for its wide practice of induction and Caesarean section, he found himself inducing labour to a very much less extent. By inducing labour two or three weeks before term very little was saved in respect to the size of the head when subjected to moulding; and the question was whether, if the head was to be moulded, it was better that it should be the premature head at thirty-seven weeks or the more mature head at forty weeks. He disliked trial labour, and never did it; it was a confession of failure of judgement. Trial labour followed by Caesarean section was bad for the mother and the infant, and the performance of Caesarean section after the introduction of bougies was even less defensible.

Mr. VICTOR LACK said that at the London Hospital during the last four years they had given up induction for a minor degree of disproportion, and had been quite well satisfied with the results. To say that trial labour meant that a case had not been investigated was hardly justifiable. He agreed with Mr. Bourne that to start a trial labour was a very serious undertaking, but he did not consider that, properly conducted, it was to be deprecated.

Dr. J. S. FAIRBAIRN thought it clearly established that there were a great many unnecessary inductions, just as there were a great many unnecessary Caesarean sections. But induction had the advantage over Caesarean section in that something could be learned from it about the labour, whereas nothing at all was to be learned from Caesarean section. He was sure that trial labour could be worked successfully, but it was a measure which called for wide experience, and also hospital equipment. Hence it had a limited application in the general run of deliveries.

Dr. J. M. WYATT thought that teaching hospitals should teach their students a method which it would be possible for them to apply in outlying districts. Induction of labour was not very difficult, and the results both to

mother and infant were good provided it was done at the right time. Induction followed by forceps had a high foetal mortality, but induction not followed by forceps had not.

Dr. R. KELSON FORD pointed out the importance, in some parts of the country, of the industrial efficiency of the mother. In an industrial community it had been his experience that the people were very much against an operation. They would rather lose the baby than have an operation which meant a longer time in bed and away from employment. That was, prima facie, an argument in favour of induction, other things being equal.

Mr. L. C. RIVETT pointed out the curious disparity in the figures presented. The London Hospital, out of 5,284 deliveries in three years, had had only 45 deliveries for contracted pelvis, whereas Queen Charlotte's, with 10,646 deliveries had had 1,285. It was difficult to decide what was meant by a minor degree of contraction. The diagonal conjugate was of very little value. It all depended on the size of the foetal head and the amount of flexion.

Mr. D. W. ROY had been surprised to find how well the moderate use of induction came out, within the limitations of the statistics. He thought it played a most useful part in treating moderate degrees of contracted pelvis, and he was pleased that Dr. Hunter had taken the view that the children of these inductions had a much higher survival rate than many had suggested. The danger of Caesarean section increased in geometrical progression with the number of times it was performed on the patient. Test labour seemed to be useful in cases which, owing to some mischance, had passed the point at which induction might usefully have been done, and yet in which Caesarean section forthwith did not seem justified.

Dr. G. W. THEOBALD pointed out that St. Thomas's appeared to be the only hospital where they tried to estimate whether the head would go through by putting the patient under an anaesthetic. Dr. W. H. F. OAKLEY said that ante-natal deaths were not a sufficient criterion for estimating the value of any method; a record should be kept of infants during the first year of life. Dr. FRANCES IVENS-KNOWLES agreed that the induction of premature labour was not an operation to be undertaken without very careful consideration. She had seen various patients who had not done at all well because they had not been examined for cervical discharge. If induction of labour became a routine method in general practice that danger would be encountered a good deal.

Dr. BREWS, in reply, stressed the importance of pelvic measurements, and also urged that students should be taught that there were cases of labour which ought not to be delivered in general practice. Dr. HUNTER remarked that in Manchester there was possibly a higher proportion of true pelvic contractions than in London.

THE INJECTION TREATMENT OF PILES

At the meeting of the Subsection of Proctology of the Royal Society of Medicine on May 13th, with Mr. L. E. C. NORBURY in the chair, a discussion took place on the injection treatment of piles.

Mr. W. S. PERRIN said that he had used for the last eight or nine years, with considerable success, the fluid recommended originally, he thought, by Mr. Swinford Edwards, consisting of one part carbolic acid, two parts glycerin, and two parts distilled water. He customarily injected two piles at one sitting, as high up as possible, putting in the needle about a quarter of an inch. He never injected more than 10 minims of this strong solution, often 5 minims or less. No other injection into the same pile should be made within less than a fortnight. In a bad case six injections might be required. What was known as the primary type of pile, which did little except bleed, was the kind most suitable for injection treatment. The secondary type of pile, which protruded only on defaecation, and replaced itself or could be replaced by the paper, might also often be injected with hope of success, but another type, in which the pile protruded at any time, was not suitable. Among 800 cases at the London Hospital which had been treated by injection he knew of no complications, and the same was true of cases he had seen in private practice. Occasionally the patient had a certain amount of pain following injection; this he thought to be due, as a rule, to the injection of too much solution, but it occurred also after quite small injections.

Mr. W. B. GABRIEL said that simple uncomplicated internal piles which were soft and reducible could be readily cured by a few high carbolic injections. Fibrous piles or polypi, enormous prolapsing piles, or piles associated with anal fissures or fistulae, were not amenable to injection, and here operative treatment was required. He used 5 per cent. phenol in almond oil, usually 3 c.cm. A week later a firm leathery induration was felt in the quadrant injected, often extending up as high as the fingers could reach. A large proportion of cases needed only three or four injections, and many in which the trouble arose from a single pile were put right by one treatment. He considered the oily solution a marked advance in efficiency and safety. Out of 800 new cases of internal haemorrhoids seen at St. Mark's during the last two years, about 75 per cent. had been treated by the injection method. The majority had remained under observation until they were free from symptoms, and examination showed a satisfactory sclerosis. The method of injection had meant a saving of hospital beds and of the patient's time. He gave a table showing the reduction in the number of operations for uncomplicated piles at St. Mark's during the last two years owing to the increased application of injection treatment in the out-patient department. Injections produced fewer dramatic results in women than in men, and there was a plethoric type of female, seen in the period of child-bearing, in which piles should be treated only on palliative lines.

Mr. E. T. C. MILLIGAN said that he now used for injection 5 per cent. solution of phenol in almond oil. For three years he had tried 20 per cent. injection of phenol in glycerin as a routine method, but in certain cases severe reactions occurred. The 5 per cent. solution, using 3 c.cm., resulted in comparative freedom from complications. His syringe was an eccentric 10 c.cm. Record with encircling markings of 3 c.cm. amounts, and he used a long injection needle. It was only fair to point out that secondary haemorrhage and pain was as frequent and severe after big injections as after operation, and much more difficult to explain to the patient. The site of injection was also important; if too low, discomfort and pain would arise. The knee-chest position was desirable, and it was important that the rectum should be distended with air. Another point to bear in mind in comparing methods was that if injection treatment had been improved, so had the technique of operative removal, and in competent hands operation was as free from complication as were injections.

Dr. CUTHBERT DUKES discussed, with the aid of drawings, the anatomy of the rectum and anal canal, and the relationship of the different structures, and Mr. C. I. N. MORGAN added some further remarks on the anatomy, pointing out that the internal haemorrhoidal plexus, which was fairly constant in position, extended upwards above the level of the internal sphincter

Sir CHARLES GORDON-WATSON stated that for his own part, in spite of having urged his colleagues to use the new injection of 5 per cent. phenol in almond oil, he

himself had not used it, finding that he had got on very well with the old carbolic-glycerin solution, which he used at a strength of 15 per cent. carbolic, neither more nor less, and he very seldom found that he required more than three injections to get rid of a pile. In pre-war days, when he had an out-patient department, he never favoured injections, having been deterred by seeing one case in which very serious complications had arisen. Since then, however, reassured by the experience of his colleagues, he had used injection treatment, but he had not had an opportunity of carrying it out on large numbers of out-patients. He had to admit that there were complications with injections, and he was amazed at the London Hospital record of 800 cases without, as far as was known, any complication. Sometimes too much fluid was given, and the patient suffered pain, and there was a little sloughing. A number of patients appeared to have pain twenty-four hours after injection. He had not seen any serious haemorrhage or sepsis.

Mr. A. S. MORLEY expressed surprise at the unanimous approval which this method was now receiving from proctologists. He had been working on the subject since the early days of the war, when there was great hostility to injection treatment of all sorts. He first employed a 20 per cent. carbolic solution, and he got very good results, but occasionally there were complications. Haemorrhage occurred, perhaps, once in 200 cases, but it was sufficient to make one hesitate. Then he heard that in America 5 per cent. carbolic was given in a certain vegetable oil (he believed copra seed oil or something similar), and he adopted this method, using almond oil. The oil had to be vegetable, not mineral, because mineral oil was not absorbed quickly enough. With regard to the instrument, he had tried various slotted speculums, with no great satisfaction, and he now used Kelly's speculum, the end of which was bevelled off so that one side was longer than the other. The longer side held back the part of the rectum on which one was not working, and kept it out of the way. His speculum had a Z-shaped handle, so that it was well out of the way of the buttocks. He used an eccentric Record syringe, with a special needle, bent at an angle at the upper end, because that kept the point of the instrument under the eye, and the rest of the instrument and one's hand did not get in the way. He preferred the knee-elbow position, and used it wherever possible in men ; in women, the left lateral position was his choice. The site of injection should be as high as any loose mucous membrane could be detected. As to complications, pain occasionally occurred, which meant that there had been too much or too frequent injection. Severe pain was experienced perhaps in one case out of 500 ; it was due to some error of technique. He disagreed with previous speakers as to choice of case. In his view there was no case of uncomplicated haemorrhoids which was unsuitable for treatment by injection, and the old-fashioned operations of ligature and cautery ought almost to be relegated to the dust heap. Fistulae, the presence of fibroid polypi on stalks, and gangrene were the only contraindications. He had treated many patients in whom prolapse was reduced with great difficulty, and the piles came down as quickly as they were released from pressure, but even here prompt injection kept them up, and they did not come down again. He had written to some 300 patients who had been treated three or four years previously, and found that 83.4 per cent. were free from recurrence. These patients had been treated by means of the 20 per cent. carbolic solution ; he had not the figures as yet showing the results of treatment by the later method. Another point was that patients did not object to a second series of injections, whereas they did object to a second operation.

Mr. KENNEDY MURPHY said that only simple uncomplicated piles were suitable for injection—that is, haemorrhoids in which the veins were not very much sclerosed, and in which there was very little fibrous tissue. Carbolic acid and glycerin could not be expected to get rid of fibrous tissue ; on the contrary, this agent increased it. The cure by injection would depend on the closeness of approximation to the most satisfactory operative procedure—namely, the ligature operation. Mr. ASLETT BALDWIN had been using urea and quinine injections and found them very satisfactory. Mr. TURNER WARWICK had found phenol and almond oil no more satisfactory than 20 per cent. carbolic. Glycerin solutions should be used both on the pedicle and the pile. The PRESIDENT pointed out that in some cases a combination of methods gave a better result than any single plan of injection alone. The possibility of pain after injection was important to remember ; there need be no pain after ordinary surgical operation for piles.

CALCIUM THERAPY

At a meeting of the Harveian Society, held at Paddington Town Hall on May 14th, with Sir THOMAS HORDER in the chair, Dr. DONALD HUNTER opened a discussion on calcium therapy.

He said that a survey of the results of calcium administration in disease showed that as a therapeutic agent calcium had proved disappointing. The constant supply of calcium in the food and the large available store in the bones made it unlikely that the regulating mechanism ever lacked calcium for distribution throughout the body. He demonstrated by lantern slides the effects of total thyro-parathyroidectomy in dogs ; tetany was relieved by injections of parathyroid extract. He showed how the prolonged use of such injections in man raised the serum calcium and increased calcium output in the urine. This calcium came from the bones. Hyperparathyroidism was a disease of bones ; and the first operation for hyperfunction of a parathyroid tumour had been performed by Mandl of Vienna in 1925. Since that time thirty-two cases had been recorded, including four of the speaker's own operated upon by Mr. Walton. In this disease (generalized osteitis fibrosa) the serum calcium was high and the calcium output from the urine might be six times the normal. Usually no lump was palpable in the neck, but on exploration a parathyroid tumour was found. After this was removed, pains in the bones ceased, the calcium metabolism was promptly restored to normal, the *x*-ray shadows of the bones became more dense, and the patient was often saved from being a cripple. In focal osteitis fibrosa evidence of hyperparathyroidism was lacking, and operation on the neck was entirely unjustified, even if many bones were affected. Whereas in hyperthyroidism bones lost calcium by a process of excessive osteoclastic resorption, the bone changes in osteomalacia and rickets were due to a failure of calcification of osteoid tissue. This had nothing to do with the parathyroid, but was due to the lack of the powerful calcifying substance vitamin D. The problem of osteomalacia in China and India was rendered difficult by religious and other customs, but the main factors in its etiology were inadequate diet and lack of sunlight. The tetany of osteomalacia and rickets should be treated by large doses of calcium lactate. In emergency, intramuscular calcium gluconate or intravenous calcium chloride should be given. Vitamin D must always be administered.

Mr. A. J. WALTON said that recent work on calcium metabolism had made it possible for a physician to say dogmatically that a parathyroid tumour was present. The parathyroids varied very widely in position. The superior pair, in his experience, were always placed in front of the thyroid fascia, between it and the thyroid

capsule. The inferior pair showed an important variation which determined the path of spread of a tumour; they might be below the inferior thyroid artery and in front of the fascia, or above the artery and deep to the fascia. Occasionally one or more parathyoids might be in the substance of the thyroid gland, and therefore certain to be removed in partial thyroidectomy. A small adenoma of the thyroid might be mistaken for a parathyroid and the true tumour overlooked. The operation of parathyroidectomy required light ether anaesthesia and a wide exposure, for the tumour might be at some distance from its expected site. He therefore made a wide collar incision, retracted the sterno-mastoids, and divided the pretracheal muscles at the level of the isthmus. The lateral lobes of the thyroid were rolled inwards in turn, and thus a tumour in the normal site of a parathyroid could be discovered at once. So far he had not had a case of tumour of the upper parathyroid bodies, and the real difficulties had arisen from the relation of the inferior pair to the thyroid fascia. If the body lay between the fascia and the capsule of the thyroid, the tumour would enlarge downwards along the thyroid veins and in front of the carotid artery, like a retrosternal goitre. If the parathyroid was behind the thyroid fascia, no sign of the tumour was perceptible from in front, and nothing could be felt by passing a finger into the thorax on either side of the trachea. The tumour was then found as soon as a small incision was made through the fascia above the inferior thyroid artery. In one case a small mass in the lower part of the right lobe of the thyroid had been removed. Professor Turnbull had reported that it was an adenoma, and not a parathyroid tumour; but Dr. Hunter had been convinced from his biochemical studies that a parathyroid tumour was present, and a second operation had therefore been undertaken. A small typical parathyroid tumour had been found behind the oesophagus and removed; a finger had been inserted into the wide space thus revealed, and a large kidney-coloured tumour, the size of a plum, found immediately in front of the second and third dorsal vertebrae. This case had shown that an enlargement of the inferior thyroid body, when situated behind the thyroid fascia, passed down behind the oesophagus into the thorax, quite out of sight. The surgical after-treatment was the same as for thyroid adenoma, but careful attention had to be given to the blood calcium estimation, and tetany must be prevented by the administration of calcium and parathormone.

Professor TOM HARE mentioned the condition of aphosphoria, which was characterized by a deficiency of inorganic salts. He was not satisfied that rickets in animals was always due to a lack of vitamin D, as a certain number of cases would not respond to vitamin treatment. He thought there might be some hereditary factor behind this failure; from the histological point of view the cases might be examples of osteitis fibrosa and not of rickets; but he had never seen a parathyroid tumour in an animal.

Dr. HUNTER, in reply to a question from the Chairman, said that calcium was beneficial in some cases of urticaria, and should not be withheld merely because its use was empirical. Oedema had been removed by parathyroid hormone. In cases of poisoning by carbon tetrachloride, necrosis of the liver occurred only if the blood calcium was low; calcium probably exerted some protective action on the liver. In eclampsia, intravenous glucose was useless without the addition of calcium. Calcium also relieved various colics, including lead colic, ureteric colic, and other cases where smooth muscle was involved. Biochemistry, he concluded, might be just as helpful as histology in the differential diagnosis of diseases of bone.

Reviews

A SYSTEM OF BACTERIOLOGY

In previous issues of this *Journal* six volumes of the *System of Bacteriology*[1] have been reviewed. Of the three remaining, volume vi is devoted to the subject of immunity, and may therefore be said to be one of the most important of the series. It opens with a chapter by H. B. Maitland on bacteria in relation to disease, which is disappointing in some respects. We should have thought that more might have been made of the question of the origin of pathogenic species—the evolution of disease—though admittedly the paucity of facts makes this question highly speculative. The conception of bacteria in the intestinal contents as living *in* the host is, of course, incorrect, though a mistake which is commonly made. Natural immunity is not a theme which lends itself to brief exposition, but J. C. G. Ledingham in Chapter II has given a most excellent account of the subject. We are still very ignorant on this question, but the difficulties with which the problems are hedged round are perhaps some excuse for lack of knowledge. A feature of this chapter is the section devoted to Besredka's recent investigations of local immunity, which are dealt with in an impartial and critical manner. The next chapter on the production of active immunity to bacterial and virus infections, contributed by J. C. G. Ledingham and H. Schütze, is also very good. It would appear that as a general rule vaccines of living bacteria produce a more solid immunity than killed vaccines, and in this respect bacteria and filterable viruses show little difference, a point not commonly realized. The bearing of recently acquired knowledge of antigenic structure on the problem of active immunization makes most interesting reading. Chapter IV, by A. T. Glenny on active immunization with toxin, could hardly fail to be of great value, coming as it does from one who has had such a vast experience.

An account of the physiological action of toxins by J. W. Trevan (of necessity brief because our knowledge of the subject is so incomplete) is followed by a consideration of antigens and antibodies and the various immunity reactions. Knowledge of antigens and antibodies has been gained by a variety of methods: from the observation of their activities and reactions both in the living body and in the test tube, from a study of their chemical nature, and from a consideration of their reactions in the light of physical chemistry. The first of these lines of approach has given us a wealth of valuable facts, which are most ably presented in this ... volume in a series of chapters by R. ... C. ... H. Browning, J. A. Arkwright, and H. R. Dean, each of whom speaks with the authority gained by long and fruitful research. Although this type of immunological investigation can still be pursued with advantage, it is recognized that without the aid of the chemist and physical chemist much would remain unsolved.

In Chapter VII P. Hartley gives us an excellent survey of the activities of the chemist in this field. It is a very clear account, and leaves no doubt of the great practical value of the knowledge that the chemist is unearthing. The bearing of physical chemistry on immunological problems is a most important one, and should, in consequence, receive serious treatment; D. Steabben's chapter on this aspect of the subject is disappointing, and, in our opinion, quite inadequate. The chapter on anaphylaxis and related phenomena by W. M. Scott is excellent; we

[1] *A System of Bacteriology in Relation to Medicine*. Medical Research Council. Vol. VI. London: H.M. Stationery Office. 1931. (Pp. 558. Single volumes, £1 1s. net; set of nine volumes, £8 8s. net.)

have rarely read such a clear exposition of anaphylaxis. The volume closes with a valuable chapter on chemotherapy by C. H. Browning.

THE CONTROL OF MALARIA

In the majority of tropical countries, and in many temperate regions as well, malaria, its control and eradication, is an ever-present problem which is bound to come under the notice of the medical practitioner, no matter within which branch of medical science may lie the scope of his activities. How, then, is an estimate to be made of the prevalence of the disease; how may one determine in any given area which is the prevailing anopheline vector; and in what manner can steps be taken to lessen the incidence of the disease? All these and other questions are answered in the excellent work on malariology which Dr. MARK BOYD describes too modestly as an "Introduction" to the subject.[2]

It can be stated very briefly that the usefulness of this book is due to the fact that the author has presented within the compass of one publication all the essential features which, previously, had to be extracted from a wide range of textbooks, periodicals, and reports often not readily accessible to officers in the field. Such a book can and will be recommended with every confidence to the student and the beginner; the experienced malariologist will recognize its value at first sight. The general scheme is well planned. There are six sections in all, beginning with an introductory chapter which deals chiefly with the historical side of the work, especially in the New World, showing how, in many regions, there has been a fall in the incidence of malaria, and giving the reasons for that decline. The geographical distribution throughout the world is dealt with briefly but efficiently, and also is shown, in graphic form, by the aid of maps, to lie between the northern and southern isotherms of 60° F. Another particularly useful map indicates the various regions within which the three species of malarial parasites are endemic.

Within the limited space available it is impossible to do full justice to the wealth of material which the author has collected into the compass of this book, though it must not be imagined that the subject loses in any way from this condensation. All the facts are clearly expressed, and the text is easy to read. In the second chapter, for example, a useful account is given of the various types of fever, the relation between the number of parasites in the blood and the fever (the pyretogenous level), which anism of relapses, recrudescences, and recurrences, frequent inje... vexed questions of resistance, immunity, and toler... case out ... due importance is placed on the enlargement of the spleen, ... agreed the various influences which may modify that enlargement, the relation between the size of the spleen and the degree of anaemia, and the effect of treatment in causing a reduction in the bulk of the organ. An interesting account is given of the current state of knowledge with regard to the infectivity of the parasites in any given host towards anophelines, and the various factors that appear to have a bearing on the production of individuals who are what may be termed "good infectors" of mosquitos. The period of invasion, which may vary considerably in its clinical manifestations in different persons, is discussed in full. Before leaving this chapter on the natural history of malaria, mention must be made of the section on malaria prevalence, where a comprehensive view is taken of all the factors having a bearing on the production of endemic or epidemic conditions. The urgent necessity for such a broad outlook in malaria control is a matter on which Boyd rightly lays great emphasis. Chapter III is concerned with the methods of undertaking malaria surveys. The author draws attention to the fact that such surveys, for a multitude of reasons, can be carried out only on parts of the total population, and therefore that the "sample" surveyed should be as representative as possible. The sections on the estimation of the "splenic rate" and the "parasite rate" are particularly valuable from the practical point of view. In the former the various methods adopted by different workers of measuring the size of the organ are enumerated in detail, while the section on the parasitology is accompanied by a coloured plate illustrating the forms of the three malarial parasites in the blood of man.

The final chapters treat in turn of the "natural history of anophelines," "anopheline surveys," and the "relation of surveys to control work." The last of these is very short, and we feel that out of his ripe experience the author might advantageously have given more on the various practical steps to be adopted in malaria control. This is not intended as an adverse criticism, for in the one volume has been included all that could reasonably be expected; rather is it a suggestion for a future publication. Indeed, it may be said that in the excellent description of the biological characters of the vector, and in the detailed account of the conduct of anopheline surveys, Boyd has laid the essential foundation on which to base the subsequent measures of eradication.

SOCIAL PROGRESS AND HEALTH

The Halley Stewart Lectures, 1930, were delivered by Sir GEORGE NEWMAN, and have now been published in book form under the title *Health and Social Evolution.*[3] They assist in the study of Christianity in its "explicit and implicit application to the social relationships of man: for every individual by furthering such favourable opportunities as shall enable him most perfectly to develop body, mind, and spirit; in all social life, domestic, industrial, or national, by securing a just environment." They set out a clear and fascinating story in an admirable form and in an eloquent and beautiful style. Leading up to their main object of describing modern collective humanism at work in health services, and of counting, if possible, the national gains and losses up to the present time, they describe how England learned to control disease in the Middle Ages and in Tudor times, what the eighteenth century contributed to humanitarianism and to medicine, how the industrial revolution affected health problems, and how the coming of democracy and a more modern spirit have led to the health work of the State, the local authority, and the medical profession to-day.

This volume is intended primarily for the wide educated public interested in social problems and in public health, and Sir George Newman has again performed a useful service, both to the public and to the members of his own profession, in his wise presentation of the true relation of the medical profession to national health organization and those social movements with which it is intimately and increasingly associated. Two quotations will illustrate his message and his exposition.

"It is sometimes alleged that the State has captured the medical man and drawn him unwillingly within by its tentacles. But the facts of the last two hundred years suggest a truer interpretation of the relation between the State and the doctor. . . . From the beginning of the nineteenth century the Government has on innumerable occasions called in the doctors to advise on the nation as patient. . . . It has desired advice from those most competent to give it. . . . I know of no evidence that the State has captured the doctor, but it has, wisely enough, captured his goods. The medical

[3] *Health and Social Evolution.* By Sir George Newman, K.C.B., M.D., Hon. D.C.L., LL.D. London: G. Allen and Unwin, Ltd. 1931. (Pp. 200. 4s. 6d. net.)

man in Britain has not withheld his goods. Two generations ago the British system of public health was unique among the nations of the world. Why was this? Other nations were equally advanced in civilization, but in Britain the medical man had been called in and had willingly responded. He responded because he shared with other citizens that remarkable genius and instinct of public spirit and public service which has built our island history. . . . It was the general practitioner who in the eighteenth century laid the foundations of State Medicine. But it has been the social evolution of the nation which has given him the opportunity. . . . If he had been in Germany, France, Russia, or Italy, he would have found no social vehicle or scope for his public ministrations. Because he was in Britain, and within the elastic walls of its constitution, he arrived. Thus the State and the doctor have mutually co-operated with each other. . . . The doctor has joined in the national movement of collective humanism in behalf of the expansion and application of science to the betterment of man's estate. His sporadic and intermittent contribution has slowly become an organized national service."

"It became necessary to recognize that the doctor could only rightly and effectually serve the State if his individualistic and inductive characteristics were respected and safeguarded. Some principles governing the doctor's service to the State (as distinct from his medical practice on behalf of his private patients) had therefore to be considered and acknowledged. For instance, (*a*) that a doctor should not (except perhaps in time of war) be compelled to serve the State, as a doctor, against his will, for the simple reason that he could not practise medicine effectually except by his own free will and judgement; (*b*) that any medical or surgical advice given by him should be what he deems by the best exercise of his skill to be appropriate to the occasion, and not a treatment prescribed or restricted by the State; and (*c*) that between the doctor and his State-provided patient there should be as far as practicable mutual freedom of choice; that is to say that, apart from 'mental' or juvenile persons, the patient chooses his doctor or his hospital, and is not subjected to a doctor of whom, or of whose treatment, he does not approve. Let me put this into one word, a public medical service should never convert the medical profession into a branch of the Civil Service, for that would thwart or stultify the value of the particular service the doctor could render."

In his relatively short review of the problem of infant mortality, of the school medical service, of the health insurance system, and of the protection of motherhood, Sir George Newman clarifies the position by getting down to the essential features of each subject, and by his wise and careful comments it is to be hoped that he will be proved to have helped both the medical profession and the public to judge the situation intelligently, and to dismiss as negligible some of the wild statements on all these matters which are from time to time made by persons who, though they assume authority, have little or no practical experience of the subjects on which they speak. Finally, Sir George Newman does well to remind us of the health work of the League of Nations, and to emphasize the fact that health is, after all, a matter of individual responsibility, that "it is not the State that can or should give us all good things," and that "a public health service can only be effective if it is received and practised by an enlightened people."

SURGERY FOR THE GENERAL PRACTITIONER

Die Chirurgie des Praktischen Arztes,[4] by Professor ERICH SONNTAG of Leipzig, belongs to a class which it is very difficult to define and criticize. Such books are more common in Germany than in England. While they do not aim at a complete exposition of the subject, yet they pretend to be much more than works on minor surgery, and, generally speaking, they err on the side of over-ambition. Professor Sonntag's is a case in point. It contains nearly 900 pages and weighs (unbound) 5 lb., without professing to offer a complete presentation of the science and practice of surgery, and there is much in it that can hardly be turned to useful account by the average general practitioner, even in Germany. What this book offers to us, however, is in the circumstances good. Professor Sonntag knows his subject and how to set it forth.

The subject is considered in two parts, general and special, and the former occupies 400 pages. In examining such a book the reviewer naturally turns to the descriptions of some of those injuries and diseases which are most likely to come into the hands of general practitioners, and to the instructions given for their treatment; for on the prompt and correct treatment of these their reputation or even their living may depend. Less than five pages are devoted to fractures of the humerus, without any illustrations. Fractures of the lower end of the radius, including Colles's, fare better, and are illustrated by four figures. All kinds of fractures of the femur are dismissed in six pages of print, without illustrations. The Thomas splint is only referred to and represented as used after amputation. Internal derangements of the knee-joint receive very cursory notice. Fractures about the ankle, including Pott's, receive more attention, but are not illustrated, though the description of the procedure of putting up such a fracture in gypsum is careful. Appendicitis seems to interest the author more than fractures; incisions for the operation for its relief are described and illustrated; we presume it is by an oversight that the bare fore-fingers are represented as inserted into the abdominal incision. A striking feature of the book is its dearth of reproductions of *x*-ray pictures, although the importance of Roentgen films is insisted on generally. On the other hand, there is a photograph of a pair of ordinary nail scissors recommended for the care of the surgeon's hands, and illustrations are included to show how a sister in the theatre should and should not hold a bowl.

A HISTORY OF THE AMBULANCE MOVEMENT

In the eleventh book of the Iliad there is a reference to the principles of first aid. It was, however, practised long before the days of Homer, for, as Dr. CORBET FLETCHER says in his record of the St. John Ambulance Association,[5] "the history of the ambulance movement is the history of the world." The author presents us with a simple but carefully compiled diary of events, not only in the work of the association since 1864, but also in that of all the other kindred organizations. He has traced the gradual development of first-aid training in the police forces, on the railways, and in the mercantile marine. Many of the chronicled events occur on red-letter days in the history of the movement—for example, the designation, on December 14th, 1909, of No. 1 District of the Brigade as the "Prince of Wales's Corps," in recognition of "the valuable services rendered by the Brigade generally, and especially by the Metropolitan Corps, on so many public occasions in London, the metropolis of the Empire." This is a commendable publication, concise and full of information, with a good index and appendices concerning the personnel, honours, competition records, and textbooks of the association. We suggest that the page headings might give some indication of the principal item mentioned below; no doubt this will be considered in future editions. The volume should prove valuable to all interested in the subject of first aid, but especially to the rank and file of the association, to whom it is dedicated.

NOTES ON BOOKS

In the preface to *A Handbook on Diseases of Children*[6] Dr. BRUCE WILLIAMSON indicates that he has tried to provide a "short but complete account of the diseases and disorders of infancy and childhood" for the student, the practitioner, and the post-graduate working for a higher examination. The book is certainly short, but success cannot be recorded for the other claims. Prematurity and diseases of the newly born receive no mention, and the treatment of many subjects is sketchy. For example, in the section on scurvy, haematemesis is stated to be "fairly common," whereas in fact it is a rare symptom, while the almost constant presence of red blood cells in the urine is not recorded here; although it is mentioned under the diagnosis of acute nephritis. In recommending sodium salicylate for the treatment of rheumatism, the author mentions the addition of sodium bicarbonate to the mixture only in the "formulary" at the end of the book, and not at the place where the inquirer would naturally look—namely, under rheumatism. In many places the phraseology is either vague—as, for example, under the treatment of summer diarrhoea, when it is advised to give saline "into the fontanelle"—or slapdash—as in the statement that "purpura has a hundred and one causes." The chapters on disorders of the heart and circulation reproduce much of Dr. G. A. Sutherland's valuable teaching, which will be, perhaps, new to those not actively engaged in the study of diseases of children.

Miss R. M. SIMMONDS'S *Handbook of Diets*[7] is a most useful volume, which will prove of great assistance to those responsible for treatment of patients, both in private practice and in institutions. It includes a table giving the carbohydrate, protein, and fat content of a large number of common foodstuffs, many prescriptions and recipes, specimen diet sheets, and useful tables. Miss Simmonds is to be congratulated on producing a very concise and satisfactory handbook.

Dr. I. FISCHER'S work on Proper Names in Nosological Terminology,[8] which is reprinted from issues of the *Wiener medizinische Wochenschrift* of the last two years, is appropriately dedicated to Lieut.-Colonel Garrison. It contains, in alphabetical order, a list of eponymous diseases, with a short account of the author who first described the disease, and references to his original description, from which a short extract is occasionally given, and to other historical articles on the particular disease. The work forms a valuable supplement to the ordinary medical dictionary, in which space forbids more than the briefest mention of eponymous diseases.

The *Pharmacopoeia of St. Thomas's Hospital*,[9] of which a new edition has just appeared, is at least as compact and comprehensive as any other work of its kind, and will no doubt prove of much service to students, past and present, of the hospital.

The biographical sketch of Brown-Séquard and his Work,[10] by Dr. F. A. ROUGET, president of the Mauritius Medical Society, represents a token of respect offered by that society to the memory of its most distinguished president of honour, who was not only an eminent neurologist, but also the founder of endocrinology. The book is divided into seven parts, dealing respectively with Brown-Séquard's life, family and marriages, the question of his nationality, his character, his scientific work, tribute to his achievements, and a list of the numerous distinctions conferred upon him. The appendices contain a variety of miscellaneous information about Brown-Séquard, including recollections and appreciations of him by his pupils and friends.

The Temple Press, Ltd., has published, at the price of 2s. 6d., a fifth edition of *The Motor Electrical Manual*. This illustrated handbook and guide for motorists describes in simple language the principles, construction, and working of electrical appliances used on cars.

The *Handbook*[11] offered by Messrs. T. P. M'DONALD and GEORGE DAVIE as a guide to the complexities of the Contributory Pensions Acts of 1925 and 1929 is a laudable attempt to bring light into dark places, and will doubtless be welcomed by those who may be called upon to advise potential beneficiaries as to their position under the Acts. After reading it we can well believe, with the authors, that "many people are in doubt whether the Act of 1929 has conferred upon them any right to a pension."

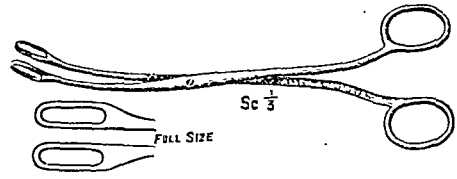
PREPARATIONS AND APPLIANCES

COMMON DUCT FORCEPS

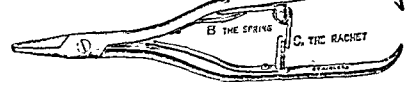
Mr. CHARLES KINDERSLEY (Bath) writes: Having been struck by the fact that the blades of Desjardin's common duct forceps were usually smooth when closed, and presented some comparatively sharp corners when open, I asked Messrs. Allen and Hanburys Ltd. to make a pair to my own design.



The only difference in the new pattern is that all the projecting corners have been eliminated, the gripping surfaces of the jaws being the same. When the forceps are applied to a stone in the bile ducts or the ureter they cannot injure the mucous membrane. This sometimes happened with the old pattern.

A MODIFICATION OF MAYO'S NEEDLE HOLDER

Dr. R. C. MACPHERSON (medical superintendent, St. Mary's Hospital, Milton, Portsmouth) writes: In using the original Mayo's needle holder for deep abdominal work I have recently found that the small knob on the handle with the thin steel wire spring becomes weak and inefficient with constant use, and eventually breaks. This causes the grip on the needle



to become loose, and I have asked Messrs. Maw to make a modification, which I consider adds surety and safety to the grip on the needle. The modification consists of a powerful spring band attached to the inner surface of the handle (as illustrated), which gives a much firmer bite on the needle and a firmer engagement of the hook on the ratchet of the other blade. This improvement has to be felt in practice to be fully appreciated. The old spiral spring of the original Mayo needle holder is much too flimsy. It gets out of order in such a way that the hook does not properly engage on the ratchet, and the slightest accidental touch on the knob sets free the catch, so releasing the grip on the needle at the most inopportune moment. The new spring requires a firm, deliberate pressure on the knob to release the needle, which cannot be done accidentally.

SATURDAY, MAY 23rd, 1931

THE PROPRIETARY MEDICINES BILL

We print in our *Supplement* this week the full text of Mr. Somerville Hastings's Proprietary Medicines Bill. Whatever its ultimate fate (and it is at least clear that it can make no progress this session) the Bill should prove a useful instrument of education if it can secure the publicity it deserves. Its provisions fall into three groups, dealing with compulsory registration of remedies, total prohibition of direct distribution to the public of remedies for certain scheduled diseases, and elimination of some undesirable forms of advertising. Of these the first group is the most controversial. It has been argued on the one hand that disclosure of ingredients to the purchaser should be a condition of sale, and on the other that in the case of medicines declaration of the inclusion or absence of any ingredient named in the schedules to the Poisons and Pharmacy Acts should be a sufficient safeguard, and that control of appliances is unnecessary. The Bill rejects both these alternatives in favour of the original proposal of the Select Committee—namely, confidential communication of formulae to the authority for registration and the deposit of specimens with the authority in the case of appliances. In the absence of any indication that public opinion would support publication of formulae this middle path is clearly the way of wisdom. Disclosure of ingredients mentioned in the schedules to the Poisons and Pharmacy Acts would do no more than will be provided by the Pharmacy and Poisons Bill now under discussion, and would not touch the main evil. Nor is it desirable to suggest either that the dangers of indiscriminate medication are confined to scheduled poisons, or that deliberate fraud may be tolerated so long as no direct danger to health arises. Further, nothing short of the confidential communication of formulae and deposit of specimens can enable the authority for registration to pass judgement upon the propriety of the therapeutic claims advanced and the directions for use issued with any proprietary remedy as he is required by the Bill to do, or safeguard the public against variations in the composition of a remedy from year to year or month to month, to suit the economic convenience of the proprietor.

Registration of appliances involves some practical difficulties, but it seems no less desirable than registration of medicines. Indeed, since the publication of the Select Committee's Report, the position as regards appliances has been altered for the worse by the multiplication of "electric" and "radio-active" frauds on the one hand, and of effective and therefore potentially dangerous electric or radio-active appliances and numerous forms of apparatus for light treatment on the other. In all these cases there ought to be some check upon the claims made and upon the directions for use. If any further reasons are needed for controlling appliances as well as medicines it may be pointed out that to control the latter and leave the former free would merely divert the unscrupulous proprietor from one field to the other. In dealing with the total prohibition of the sale and advertisement direct to the public of remedies for certain specified diseases the Bill follows the amendments made by the House of Lords in Dr. Addison's Bill, in preference to the recommendations of the Select Committee. The original proposal was to prohibit the sale of "all remedies stated to be effective for the prevention, cure, or relief of cancer, consumption, lupus, fits, epilepsy, amenorrhoea and other diseases peculiar to women, diabetes, paralysis, locomotor ataxia, Bright's disease, deafness, and rupture," but it was pointed out in discussion that there is a legitimate field for the exploitation of appliances for the relief of deafness and rupture, provided exaggerated and misleading claims are excluded. Accordingly the prohibition in the new Bill is made applicable to medicines and surgical appliances held out as effective for the "cure" of deafness or rupture, or the "prevention, cure, or relief" of the other diseases enumerated above. Any alteration by the Minister of the scheduled list of diseases is made subject to the approval of both Houses by resolution.

In the provisions designed to eliminate undesirable forms of advertising, the Bill embodies certain clauses not included in Dr. Addison's Bill of 1920. Of these it may be said at the outset that none goes beyond the spirit of the recommendations of the Select Committee, and some would give effect to specific recommendations of that body which seem to have been overlooked when the earlier measure was drafted. Thus the Select Committee recommended prohibition of all advertisements of remedies for diseases arising from sexual intercourse or relating to sexual weakness, and also of any advertisement suggesting that an article might be used or might operate as a means of procuring abortion or miscarriage. The first of these prohibitions was omitted from the Addison Bill, possibly from some erroneous idea that the point had been covered in the Venereal Diseases Act. Its importance needs no elaboration for anyone conversant with widely circulated advertising literature of this class, and it is included in the present Bill. Another useful addition is the clause which defends professional publications from misquotation in advertisements by requiring that any reference to an alleged recommendation of a proprietary remedy in such a publication shall be authenticated for purposes of verification by mention of the name, date, and page of the publication quoted. For the rest the Bill follows the recommendations of the Select Committee in penalizing publication of a false trade description of any proprietary remedy, and thus goes further than the Addison Bill.

As we have already stated the Bill is, in our opinion, well drawn, but we regret that so unfavourable a time has been chosen for its introduction. Proposals for the control of traffic in proprietary remedies must inevitably meet with an opposition whose bitterness and strength correspond to the magnitude of the material interests affected. But the Bill is open to attack from another angle. Any scheme of registration must involve not only the erection of a new authority or an addition to the existing powers of the Ministry of Health, but also an addition to the ranks of the Civil Service, for the purpose of carrying out the requisite inspection and analysis and the examination of therapeutic claims and directions for use. This is hardly an auspicious moment to propose either new powers for a Minister or additional public outlay. That objection, however, is inapplicable, or applicable only in a minor degree, to the provisions prohibiting the sale and advertisement of remedies for the scheduled diseases, and those for the regulation of advertising. The issue as regards the former group is clear, and must be faced on its merits; it cannot be avoided by an appeal to economy or to the fear of departmental tyranny. Concerning the latter, we have reason to believe that the proposals for the better regulation of advertising would in the main have the whole-hearted support of the Advertising Association and of that section of the press which already tries to discriminate between legitimate and fraudulent or dangerous advertising and finds real difficulty in doing so. We suggest, therefore, that the sponsors of the Bill might be well advised to consider the possibility of withdrawing, for the time being, the clauses that deal with registration, and to concentrate upon the less controversial clauses that deal with the scheduled diseases and the regulation of advertising. This is emphatically a case in which any advance is better than no advance at all; and there seems no ground for supposing that the ultimate fate of any scheme of registration to be introduced at some more favourable opportunity would be in any way prejudiced by the immediate success of the partial measure we suggest.

HUGHLINGS JACKSON

We publish on another page this week a letter, signed by a number of representative physicians, surgeons, and scientists, appealing for support for a fund which it is proposed to raise with a view to commemorating the name of Dr. Hughlings Jackson. The Hughlings Jackson Lecture was founded in 1897 by the old Neurological Society to do honour to him as its first president, and it has been delivered triennially ever since, with some interruptions. With the money to be obtained the signatories of the letter suggest an endowment sufficient to furnish future lecturers with an honorarium, and, it is understood, also with a medal, thus enabling them to have a worthy souvenir of their official association with the memory of a man who was held in the highest esteem and regarded with the deepest affection by all who came to know him.

Jackson died in 1911, and already those who were his intimates and associates are becoming fewer, while others who came in contact with him as juniors find their memories dimmed with the passing of time. It is difficult to convey to newcomers in the field of neurology the peculiar influence unconsciously exercised by him on the minds of his colleagues and students. What his subject was like when he entered the field in the sixties of last century can be gauged by reference to contemporary literature; it was the era of morbid anatomy, with little or no serious attempt at scientific clinical observation, and still less at either neurophysiological or psychological experiment. Jackson proceeded quietly but insistently on his way; his vivid but controlled imagination, combined with the philosophic bent of his mind, resulted in the appearance of a succession of hypotheses, founded on exact clinical study, which as by a flash illuminated the workings of the brain, and served in the most striking fashion to stimulate inquiry and provoke systematic research. No better proof of this is required than the unanimity with which distinguished colleagues acknowledged their indebtedness to him, or the eagerness that animated younger men to get into personal touch with him and learn from his rich experience or become imbued with some of his spirit. As the years passed it became obvious that Hughlings Jackson had consolidated doctrines in respect of the nervous system and its functions which proved to be not merely fundamental on the scientific side, but extraordinarily fertile when applied to problems of nervous disease. To the end of his life he was instrumental in fanning the flame of research in other minds, in awakening thought and stimulating observation; and when these effects were produced by one of singular modesty and personal charm, willing and ready to see points of view other than his own, the result was to endear him to the hearts of all who were associated with him.

Yet in one sense his fame was limited: to understand his marvellous achievement required knowledge of the subject, and neurology had not then attained the prominence, even publicity, which it receives to-day. Without being aware of it, perhaps, a new generation has arisen which has entered into his labours, and the commonplaces of nervous disease and of cerebral physiology are accepted without a thought being given to the one man above all others whose genius discovered them and foresaw their significance. To commemorate in some permanent way his greatness, to secure, even if tardily, that further honour should be done to his name, to evince to younger students of the same subject that he was the fount of inspiration to their predecessors, is the purpose of this appeal. It is twenty years since he died, and if personal memories linger only with comparatively few, the spirit which animated him is undying so long as it is reborn in those that come after him and find in his work an incentive and in its emulation a reward.

SCHOOLS OF HYGIENE

The Commission on Education in Hygiene and Preventive Medicine, appointed by the Health Committee of the League of Nations in 1924, invited and received reports from a number of countries, including Great Britain. It attended conferences at the opening of new schools of hygiene at Warsaw, Budapest, and Zagreb, and in 1930, under its auspices, meetings of the directors of certain schools of hygiene were held in Paris and Dresden. The report[1] on these conferences is of interest both for the general principles it formulates and for the data it supplies regarding the scope of health instruction in Great Britain and other countries. The introductory section, by Professor Léon Bernard of Paris, recalls three principles in health organization which are regarded as vital: (1) that unless a body of trained experts is formed no public health work is possible; (2) that without the collaboration of an enlightened medical profession the work of these experts would be sterile; and (3) that without the support of the masses the precepts of hygiene would remain a dead letter. With reference to the schools of hygiene in which these experts receive their training, three further principles are laid down: (1) that there should be co-operation between schools of hygiene and universities and the public health services; (2) that the universities and public health services should be represented in the management of the schools; and (3) that the schools should combine the scientific spirit with a practical outlook. The report urges the value of research to schools of hygiene on the ground that it stimulates the intellectual activity of the members of the teaching staff and increases their influence both on their colleagues and on their students. Whether the research is pure or applied is not of primary importance. It will, as a rule, be carried out by the staff, but it may be entrusted to specially qualified students. The place occupied in curriculums by sanitary engineering will depend upon the degree of development of the general sanitation in the country concerned. In less advanced countries the subject may occupy a prominent position; in countries like ours which enjoy an established sanitary tradition it is only necessary that the student who aspires to become a medical officer of health should acquire enough knowledge of sanitary engineering to enable him to supervise the work of his sanitary inspector and to discuss with understanding plans or schemes drawn up by engineering specialists. Much weight is properly attached to "field training," by which is meant the opportunity of gaining experience of the practical aspects of hygiene. To this end visits should be made to places and institutions of hygienic interest, and the student should himself take part in the work of a public health service. Field instruction should aim at training, not teaching, and a period of not less than six months should be devoted to it. The number of teachers of different subjects in a school should be ten to fifteen. If the number is inadequate specialized instruction can scarcely be given: if there are too many the course tends to be broken up into a succession of detached lectures. Some schools provide training for auxiliary health personnel and also instruction in health matters for the general public; others confine their efforts to the training of medical officers of health. Schools of hygiene should be autonomous institutions, not necessarily closely associated with a university, but including university professors on their staffs. With regard to the health teaching of the student of medicine, as distinguished from that of the candidate for a diploma in sanitary science, the report emphasizes that in most European countries the instruction which the medical student receives is not sufficient to equip him for the proper discharge of his duties as a medical practitioner. It is confined to a theoretical outline, and does not adequately take account of the social problems involved. Throughout his curriculum the student's attention should be directed to the social aspects of medicine. The task of inculcating this lesson would fall mainly to his clinical teachers in dispensaries and out-patient departments. Arrangements along these lines, it is suggested, would function best in small teaching units; in large universities suitable schemes may be difficult to organize. In some cases it would be possible for the medical officer of health to take part in the practical instruction of students of medicine. The preventive idea should pervade the whole of the student's medical training; if this is secured he will come to his formal course in hygiene towards the end of his curriculum with a mind prepared. The professor of hygiene, who should himself have a thorough experience of practical hygiene and be a competent clinician, should urge this policy on his colleagues in the school or university. The body of the report sets forth with numerous plans and illustrations the construction, arrangement, administration, and curriculums of the schools of hygiene of London, Warsaw, Zagreb, and elsewhere. It should prove of interest to all engaged in the organization of new schools or in the rearrangement and expansion of existing institutions.

[1] League of Nations Health Organization. Report on the Work of the Conferences of Directors of Schools of Hygiene. Geneva, 1930. (1.25 dollars; obtainable in Great Britain from Allen and Unwin, Ltd., 5s.)

A NEW INTERNATIONAL CONFERENCE ON THE TRAFFIC IN NARCOTIC DRUGS

An international conference on the limitation of the manufacture of narcotic drugs will assemble under the auspices of the League of Nations at Geneva on May 27th. Representatives from all countries, whether producers or consumers only of the drugs in question, will there meet, with a view, if possible, to agree on amendments of the Geneva Convention of 1925 and to achieve the limitation of the dangerous alkaloids derived from the opium poppy and coca leaves to strictly medical uses, as contemplated by Article 9 of The Hague Opium Convention of 1912. A twenty-seven-page pamphlet has been prepared by the secretariat of the League describing the history of the movement since 1912 and the present situation. It recites the task submitted by the Assembly of the League to the contentious conferences which met at Geneva in 1924, and how the direct limitation of the production of opium and coca leaves and their alkaloids to the amounts required for legitimate use was abandoned in favour of indirect limitation by the control of imports and exports. It shows how failure to ratify, or to carry out, the Geneva Convention led, during the next five years, to an increase of the illicit traffic, till it assumed "alarming proportions." It relates the attitude of the Advisory Opium Committee,

which favoured procedure under the Geneva Convention, and that of the tenth Assembly of the League, which preferred "supplementing the Convention without delay so as to limit the manufacture of dangerous drugs to the amounts required for medical and scientific purposes." Reference is made to the limitation scheme of 1930, based on the allocation of quotas of the total world requirements among manufacturing countries, and to the failure of the London Conference of November, 1930, to agree on what the quotas should be. Further investigation by the Advisory Committee, now reinforced by representatives of non-producing countries, has shown the complexity of the problems which will confront the conference; the draft of a new convention, which is to be submitted, is clearly understood to be merely a basis for discussion, and alternative methods of achieving the desired limitation will be duly considered. The Italian, Belgian, Japanese, Turkish, and Yugoslav delegations have objections to raise or amendments to propose, while the method of dealing with contraband seizures, the control of prices, the inclusion of new drugs of addiction, and the constitution of a central organ for supervising estimates and distribution, will engage the attention of the new conference.

GLASS

Glass is of such common use that very few think what an amazing substance it is: solid, resistant, and yet able to transmit the view as though there were no obstruction between the eye and the view. But more amazing are the varieties of glass which the modern chemist has devised. In a recent lecture to the Illuminating Engineering Society[1] Dr. S. English dealt with the technical aspects of these glasses. The bands of coloured light we see in the rainbow do not represent the total radiations present in the sunlight. The same is true of most artificial sources of light. There are invisible rays at each end of the spectrum—the ultra-violet rays and the infra-red rays. According to the chemical constituents of the glass so the transmission of these rays may be varied and the invisible rendered visible. The ideal material for transmitting ultra-violet rays is silica, though it is too expensive for general use; ordinary glass contains 70 to 75 per cent., but since there are many other constituents little of these rays pass through it. Iron oxide is the chief of the obstructors; good ultra-violet glass may contain as little as 0.02 per cent. The ferrous oxide is less disturbing than the ferric oxide. In the preparation of such glass, reducing substances are included in the batch mixture to convert the ubiquitous iron to the ferrous salt. But when the glass is exposed to ultra-violet radiation, either from the sun or from an artificial source, the ferrous oxide is converted into the ferric oxide. Because of this change a glass which has a transmission of, say, 60 per cent. of the health rays when new may have this figure reduced to 50 or even 40 per cent. after its iron oxide has come to an equilibrium. The change is spoken of as "solarization"; it takes from three to six months to become complete. All commercial glasses suffer from this defect in varying degrees. Wood's glass, named after its inventor, Professor Wood of Johns Hopkins University, owes its peculiar properties to the fact that it contains a certain proportion of nickel oxide on a potash base, which is sufficient to colour the glass a very deep blue, and thus obstruct the passage of rays of visible light, but not the ultra-violet rays. By the use of a glass of this type it is possible to have a room in darkness but filled with invisible rays that only need a suitable medium for showing them up. Fluorescent solutions will do this. But there is a glass, known as canary glass from its colour, which contains 1 per cent. of uranium oxide; this has the power of converting the invisible rays into the longer rays of green light, which can be seen by the eye. Wood's glass has been very valuable in research and in applied medicine; by means of it hair from a scalp infected with ringworm shows a strong fluorescence, healthy hair does not. Genuine pearls and false ones can be distinguished, natural teeth and artificial, and so forth. It can be employed in delicate acid-alkali titration tests, with quinine as an indicator. Crookes's glass is well known and widely used. The cerium in it absorbs the ultra-violet rays strongly. It may be a nearly colourless glass, and yet filter the active rays from light to the comfort of the eyes of the hypersensitive, and for the protection of fabrics likely to fade. Everyone is familiar with the power of glass to transmit heat, of which advantage is taken in the common garden greenhouse, but a glass that will cut off all the heat rays can be produced. Crookes found that iron oxide was the most effective constituent of glass for this purpose, giving it the familiar green colour of the pre-war bottle. Glasses of this type are of great value in the Tropics, and even in this country for roofs or skylights, and they have been found of service for hospital operating theatres. By the use of such glass the temperature indoors can be kept quite cool when there is hot sunshine out of doors. The colour of the glass is not in its favour, but after a little time is spent in a room or workshop glazed with such glass the colour is not noticed. A glass the very reverse of this has been produced, which will absorb all visible rays but transmit infra-red rays. It has been of great service in invisible signalling, and it has a field of usefulness for burglar alarms and apparatus of that type.

THE BRITISH SCIENCE GUILD'S PROGRAMME

Speaking at the annual meeting of the British Science Guild, the president, Sir Samuel Hoare, said that the Guild was intended to be a bridge between the world of science and the general life of the country. Its lectures and publications showed how catholic were its interests and how practical its methods. It had, for instance, published a *Catalogue of British Scientific and Technical Books*, now in a third and enlarged edition. It had carried out an investigation into the position of the technical expert in the public services and industry; and such lectures as Sir William Pope's on "Science and modern industry" and Sir David Prain's on "Science discipline" made a considerable impression on public opinion during the past twelve months. The Guild was now anxious to embark upon a more ambitious programme, and intended to investigate the potentialities of existing industries and the effect that the proper application of science would

have upon them. In the present crisis all the help that scientific inquiry could apply was needed. Were successive Governments helping or hindering the application of science to industry? How far were reactionary employers and equally reactionary trade unions impeding progress? These were the kind of questions that the Guild wished to deal with in its inquiry. Science and disarmament was another field of investigation that he would like to see explored. The knowledge he gained at the Air Ministry convinced him that armaments was going to be the central question of foreign politics in the years immediately ahead. He believed that if the discussions at Geneva next year were to be really useful, the scientific aspects of disarmament should be brought into even greater prominence than its political and financial aspects. The main problem, and by far the most difficult, was that of the new weapons of destruction and the need for finding some means of controlling them. Should the world of science help these developments? The question was by no means a simple one, for scientists would discover new rays and gases and explosives in the stride of their ordinary work. Should gas warfare be prohibited? One school of thought maintained that gas warfare was more humane than a warfare of machine-guns and high explosives, and that the gas warfare of 1917 exhausted the future possibilities of this kind of attack. Sir Samuel Hoare did not share this view, but he maintained that scientists alone could give a true answer to the question.

CATS AND HUMAN DISEASE

There must be several million cats at present alive in this country. They live in a very intimate relationship with mankind, more intimate than in the case of any other animal, and their potentialities for the transmission of disease to human beings must be considerable. Accordingly, a recent review of the literature on the cat in relation to disease transmission[1] by D. R. A. Wharton, is of considerable interest. Cats, especially when young, may be experimentally infected with the organisms of diphtheria and of tuberculosis. There is, however, little evidence that cats frequently or even occasionally suffer from naturally acquired diphtheria; and, while they are susceptible to both human and bovine strains of tuberculosis, and have almost unrivalled opportunities for becoming infected with either, a remarkably small number suffer from this disease also. Cats do sometimes suffer from plague, and may play a part in the dissemination of this disease; and, like their masters, occasional cases of glanders, anthrax, and foot-and-mouth disease have been reported in them. Rabies occurs now and then in cats, and here the bite is probably more dangerous than that of the dog, because of the fine, needle-like teeth. Sometimes protozoa pathogenic to man are reported from the cat, and it does undoubtedly harbour a number of human helminths, especially those which, like dibothriocephalus, clonorchis, heterophyes, and paragonimus, are transmitted by fish or shell-fish. Lastly, feline mange, fleas, and ringworm are sometimes transmitted to man. The net results of the review is that, while the cat can suffer from a variety of infections which also occur in man, in actual practice, apart from acting as reservoir to a number of flatworms, its influence on public health is probably negligible.

[1] *The Cat in Relation to Disease Transmission: A Review.* By Denis R. A. Wharton. Long Island, New York: The Biological Laboratory, Cold Spring Harbor. March, 1931.

POST-GRADUATE COURSES IN TUBERCULOSIS

The Joint Tuberculosis Council has arranged a post-graduate course in Holland from June 29th to July 4th. Visits will be paid to The Hague, Amsterdam, Alkmaar, Laren, Hilversum, and Apeldoorn among other places; arrangements will be made to inspect urban and rural dispensaries, tuberculosis hospitals, open-air schools, after-care colonies, and sanatoriums, special lectures and demonstrations being given in each place. No lecture fee will be charged; inquiries about touring expenses should be addressed to Dr. W. Brand, 8, Highway Court, Beaconsfield, Bucks. A post-graduate course will be held in Lancashire from October 19th to 24th, with special relation to central administration in counties and cities, the application of actinotherapy and radiology to tuberculosis, the pathology of tuberculous lesions, treatment of advanced and chronic pulmonary cases, and pneumonoconiosis. Dr. P. W. Edwards, medical superintendent of the Cheshire Joint Sanatorium, will give, at dates to be arranged, a series of short intensive post-graduate practical courses on modern methods of treating tuberculosis of the respiratory system, with special reference to collapse therapy. Methods of sanatorium administration will also be demonstrated. No class will exceed four members in number or three days in duration, and suitable arrangements for board and residence can be made within convenient distance of the sanatorium. All communications about these courses should be addressed to Dr. Brand.

WELFARE OF THE BLIND

In view of the continued development in the work among the blind, owing to the operation of the Blind Persons Act, 1920, and the Local Government Act, 1929, and the new problems constantly arising in connexion with this service, the Minister of Health has reappointed the Advisory Committee on the Welfare of the Blind for a further period of office. The committee has been constituted so as to afford representation to the local authorities concerned with the working of the Blind Persons Act, 1920, and to voluntary associations for the blind, as well as to organized blind workers. The chairman of the committee is Lord Blanesburgh, and the medical members are Dr. A. Eichholz, Dr. S. J. C. Holden, and Dr. J. Middleton Martin. The committee will advise the Minister on matters relating to the care and supervision of the blind, including any question that may be specially referred to it by the Minister. Mr. F. M. Chapman of the Ministry of Health will act as secretary.

The Minister of Health and the Secretary of State for Scotland have appointed a committee to inquire into the working of the law as to the composition and description of articles of food other than milk, and to report what alterations, if any, in the law or its administration appear to be desirable. The chairman of the committee is Sir Frederick J. Willis, and the medical member is Dr. J. M. Hamill. The secretary is Mr. W. J. Peete of the Ministry of Health, to whom all communications on the subject should be addressed.

HUGHLINGS JACKSON MEMORIAL

We have received for publication the following letter dated May 13th, 1931:

"A fund is being raised to establish a permanent memorial to Dr. Hughlings Jackson. Among those who are taking action in the matter are many old friends and pupils who revered and loved Jackson, and who recognize to what an extent the pre-eminent position of British neurology in the medical world is due to his work and influence. He was among the great leaders of modern neurology, and it is much to be desired that the inspiration that he gave to so many in his lifetime should be kept fresh, and still serve as a stimulus to a younger generation who knew him not.

"It is hoped to raise an amount sufficient to provide a permanent endowment for the Hughlings Jackson Lecture, given every third year before the Section of Neurology of the Royal Society of Medicine. Several generous promises of support to such a fund have already been received, but the signatories of this letter feel that an opportunity to subscribe should be given to many who can only be reached through the publicity of the press, and who would certainly wish to show their appreciation of the position which Hughlings Jackson holds in the history of modern medicine. Dr. Wilfred Harris, of 56, Wimpole Street, London, W.1, has consented to act as treasurer of the fund, and subscriptions should be sent to him, marked 'Hughlings Jackson Memorial Fund.'"

This letter is signed by Sir Thomas Barlow, Past-President, Royal College of Physicians; Sir John Rose Bradford, Past-President, Royal College of Physicians; Professor Judson Bury, Past-President, Association of Physicians; Sir E. Farquhar Buzzard, Regius Prof... of Medicine, University of Oxford; Dr. James Coll..., Senior Physician, National Hospital, Queen Square; Lord Dawson of Penn, President, Royal College o... Physicians; Sir Henry Head, late Editor of *Brain*; Dr. Gordon Holmes, Editor of *Brain*; Mr. Leslie Paton, President, Section of Neurology, Royal Society of Medicine; Sir Percy Sargent, Surgeon, National Hospital, Queen Square; Sir Charles Sherrington, Past-President, Royal Society; Dr. James Taylor, Consulting Physician, National Hospital, Queen Square; Dr. S. A. Kinnier Wilson, President, Section of Psychiatry, Royal Society of Medicine; and Dr. Wilfred Harris.

FIRST LIST OF SUBSCRIBERS

The following is a preliminary list of subscribers to the Hughlings Jackson Memorial Fund.

Dr. W. J. Adie
Professor E. D. Adrian
Sir Thomas Barlow
Dr. A. Stanley Barnes
Dr. Helen Boyle
Sir John Rose Bradford
Dr. Judson Bury
Sir E. Farquhar Buzzard
Dr. Hugh Carleton
Dr. P. C. P. Cloake
Dr. James Collier
Dr. Macdonald Critchley
Lord Dawson of Penn
Dr. D. E. Denny-Brown
Sir David Drummond
Dr. Anthony Feiling
Dr. R. G. Gordon
Dr. J. G. Greenfield
Sir William Hale-White
Dr. Wilfred Harris
Dr. Gordon Holmes
Dr. Redvers Ironside
Dr. Ernest Jones
Dr. H. S. Le Marquand
Dr. Douglas McAlpine
Dr. E. D. Macnamara
Dr. Edward Mapother
Professor Pierre Marie
Dr. C. S. Myers
Dr. E. O'Flynn
Mr. Leslie Paton
Dr. S. M. Payne
Sir James Purves-Stewart
Dr. Nathan Raw
Dr. George Riddoch
Dr. A. E. Russell
Dr. J. S. Risien Russell
Dr. W. R. Russell
Sir Percy Sargent
Dr. Ruby Stern

EARLY MEN AND APES

BY

PROFESSOR G. ELLIOT SMITH, M.D., F.R.S.

During the time that has elapsed since Sir Arthur Keith last made (in 1925) a comprehensive survey of the facts relating to the antiquity of man so much of cardinal importance has happened in the domain of human palaeontology that the time was ripe for a commentary on the new discoveries. This he has supplied in the present volume,[1] which closely conforms in its methods of exposition and illustration to the well-known treatise to which it forms a supplement. It gives a very useful survey of the additions to our knowledge of Neanderthal Man and the new representatives of that species found in Gibraltar, Germany, Italy, the Crimea, and Palestine; and of the conflicting reports on the remains of more modern men from East Africa, South Africa, Australia, and elsewhere. There are also disquisitions on the excavations at Ur in Sumer, on the significance of endocranial casts, and on an acromegalic skull from a Christian cemetery of the twelfth century in Greenland, to which, with amazing irrelevance, a distinct specific rank (*gardarensis*) is accorded. This provides Sir Arthur with the opportunity for [illegible] with his familiar speculation that some [illegible] primitive men were the victims of an imaginary disturbance in the working of their pituitary glands. On this subject he still leaves us wholly in the dark as to the precise nature of his claims, and what exactly his argument is.

The major part of the book is devoted to lengthy reports on, and discussions of the significance of, the Taungs ape, first described in 1924 by Dr. Raymond Dart, professor of anatomy and dean of the Medical School in the Witwatersrand University; the Lloyds skull, representing the earliest known inhabitant of the City of London, the finding of which was recorded by Mr. Warren R. Dawson in 1925; and the most significant discovery in human palaeontology, the remains of Peking Man, with which the name of Professor Davidson Black will always be associated, though the actual fossils were found in 1927, 1928, and 1929 by Dr. Birger Bohlin and Mr. W. C. Pei. Sir Arthur Keith gives a full and precise account of the remains of the Taungs ape, and a sober assessment of their significance, with which most anthropologists are likely to agree. As his detailed statement of the evidence and his judgement of its meaning are in complete agreement with the brief summary in my *Evolution of Man* (1927), it is hardly necessary for me to say more than repeat the verdict that *Australopithecus* is an ape akin to the chimpanzee and gorilla, and even more nearly to the extinct *Dryopithecus*, which reveals a more definite, if slight, approach to the human condition than any other known ape.

Sir Arthur devotes special attention to "The Lady of Lloyds," and expresses the opinion that this earliest

[1] *New Discoveries Relating to the Antiquity of Man.* By Sir Arthur Keith, M.D., F.R.S. London: Williams and Norgate, Ltd. 1931. (Pp. 512; 18 figures. 21s. net.)

known inhabitant of London deserves much more attention than I showed her in 1925 (*British Medical Journal*), and 1927 (*Evolution of Man*). I can only assure him that I share his opinion. Sir Arthur's suggestion that the Lloyds skull should be assigned to the Piltdown type, however, is devoid of any sort of justification. Some years ago Miss Dorothy Garrod convinced me that the geologists were in error when, in 1925, they refused to admit that the fossil was as old as the Mousterian. But while admitting its remote antiquity I fail to discover in the Lloyds skull any reasons for associating it in type with the Piltdown skull. The comparison is made plausible only by the fact that Sir Arthur still persists in using his old reconstruction of the Piltdown skull, which is obviously erroneous. No one can fail to recognize the medial part of the lambdoid suture on the fossil and even in Mr. Barlow's excellent casts, which are now exhibited in many museums. Yet Sir Arthur assumes (see his Figs. 154, 155, and 157) that this part of the suture is not present, but about a centimetre distant from the fossil parietal in his hypothetical restoration. The error created by this neglect of the clear anatomical evidence revealed in the fossil is still further exaggerated by his failure to recognize the median plane (which he has put some distance to the right of its true situation), and the mode of articulation of the parietal with the temporal bone. Hence there is a profound contrast between his conception of the Piltdown skull and the reconstruction I made (see my *Evolution of Man*, 1927, Figs. 17 to 24) to give proper expression to the facts of anatomy actually displayed in the bones. The true reconstruction of the skull reveals nothing whatever to justify the claim that the Piltdown skull resembles the Lloyds skull.

In his introduction Sir Arthur Keith confesses that he wants to reopen the Piltdown controversy. It is strange that this provocative challenge should be accompanied by his old diagrams revealing anatomical errors of which he cannot be ignorant. This persistence in error becomes all the more incomprehensible in the light of the discoveries in China, for the skull found near Peking on December 2nd, 1929, reveals in an exaggerated form (particularly in the view of the brain-case from behind) those bizarre features which in 1913 seemed so incomprehensible to Sir Arthur that he felt it necessary to disregard the sutures and make a monstrous big skull. In his otherwise excellent account of the Peking skull he omits all reference to this aspect of the new fossil, which more than any other factor confers exceptional importance on the Chinese discoveries.

Sir Arthur discusses several matters that have no direct relevance to the problems of the fossil remains of man. For instance, he gives us his views on the origin of agriculture. Without citing a single fact in justification, he says: "We must give it an antiquity of some 10,000 or 12,000 years" (p. 170). Moreover, "it is certain that a knowledge of agriculture was carried into Egypt." Claims such as these, which come into conflict with all the known facts, should not be made without evidence or argument in their support. Yet such speculations as Sir Arthur does make would, if admitted, be fatal to the acceptance of the statements just quoted. Thus he accepts at their face value the strange claims for the former existence in Egypt of a so-called "Badarian" phase of culture presumed to be older than the pre-Dynastic period. These "ancient dwellers in the Fayum," he proceeds to tell us, "had come by a knowledge of agriculture, while the cave people of Palestine had no such knowledge" (p. 230). In fact, there is no evidence anywhere in Asia of the practice of farming at all comparable in age to that attributed to the Badarians. Yet he asserts that "our modern civilization, which was made possible by the discovery of agriculture, was born in the south-western part of Asia," whence it "was carried into Egypt." This purely imaginary, and certainly fictitious, version is set forth without any reference of any sort to the body of decisive evidence, which is fatal to it, collected by Professor Thomas Cherry of Melbourne while he was serving in Palestine and Egypt with the Australian Medical Corps during the great war. I need not say more of Dr. Cherry's important researches here, because I have given in my book, *Human History* (Chapter VII), a full report of his evidence and conclusions, which in my opinion settle the question once for all. But, whether or not this is admitted, the facts cited by Professor Cherry cannot be ignored, as Sir Arthur Keith has done.

Surely the last two chapters must have been included by inadvertence? An interpretation of endocranial casts which leads to the conclusion "that a large brain was given to man, not that he might understand life, or circumvent difficulties, but simply to enjoy it," can hardly be meant seriously. Why also devote a whole chapter to "The discovery of *Homo galilaeensis*," when Sir Arthur frankly admits that this individual of the new species was in fact a twelfth-century Christian afflicted with acromegaly.

In spite of these minor defects the book is an eminently useful guide to the recent advances in human palaeontology. It is as brilliant in exposition as it is entertaining in the telling of the story, and it gives just and generous acknowledgement to those adventurous anatomists Davidson Black and Raymond Dart, whose great achievements will always be regarded as outstanding events in the progress of the palaeontology of apes and men during the last decade.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held on May 13th, when the president, Mr. Warren Low, C.B., F.R.C.S., was in the chair. The annual report for 1930 showed that the membership of 285 was composed of 160 life members, 124 ordinary members, and 1 honorary member. During the year six members had died, among whom was Sir Francis Champneys, a member of forty years' standing, a vice-president, and at one time an active member of the court of directors; seven new members had been elected. The annual grant was £75 to widows over 65 years of age, and £60 to those under 65, while each orphan under 15 years of age received £50; in addition, a Christmas present of £10 was made to each widow and orphan. The sum of £241 was also paid to six orphans who had reached the age of 16, to enable them to continue their education at school or to start some professional or business career. The expenditure in grants and presents amounted to £4,963, while the expenses were £350.

The society is a mutual provident benevolent association of medical men who at the time of their admission to membership are resident within a radius of twenty miles from Charing Cross. The invested funds of the society, which was founded in 1788 and incorporated by Royal Charter in 1864, exceed £140,000. The annual subscription of a member under 40 years of age is £2 2s., and after payment of three annual subscriptions his dependants become eligible for benefits; a single payment of £21 secures a life membership to a member under 30 years of age, with immediate eligibility of his dependants for benefits. Full particulars can be obtained from the secretary, 11, Chandos Street, London, W.1.

As an instance of the benefit of joining the society, attention is called in the report to the case of a widow who had been on the fund since 1917 till her death in 1930; she had received £925 in grants; her husband had paid £31 10s. in subscriptions.

Ireland

University of Dublin

The first John Mallet Purser Lecture will be delivered in the School of Physic, Trinity College, Dublin, on June 26th, by Sir Edward Sharpey-Schafer, F.R.S., professor of physiology in the University of Edinburgh, who has chosen as his subject "The new physiology." The lecture will be open to medical students and medical practitioners. This lectureship was endowed by Miss Sarah Purser, in memory of her brother, the late Dr. Purser, who devoted his life to the welfare of the School of Physic, where he taught for many years.

The usual three weeks' post-graduate course for general practitioners, which will be held this autumn from September 14th to October 3rd, will include clinical lectures in surgery, medicine, obstetrics, orthopaedics, laryngology, ophthalmology, and diseases of the skin. Laboratory instruction will be given each afternoon in the medical school in anatomy, physiology, pathology, and bacteriology. There will also be demonstrations on the use of the electrocardiograph and of radium, and lectures on medicine and therapeutics. Members of the classes will be accommodated, as far as possible, in the College rooms.

National Health Insurance (Irish Free State)

In moving the vote for National Health Insurance in the Dáil the Minister for Local Government and Public Health said that the Act of 1929 had enabled him to make some reductions in the cost of the headquarters staff, amounting to approximately £4,000. The cost of sickness benefit, however, had become so heavy that investigation was required to see how far the increase in this item was due to laxity in certification or increased illness, or to a combination of both. In 1927 the number of cash payments, excluding sanatorium benefits, was 638,596; in 1928, 652,833; in 1929, 681,051; in 1930, 713,662—an increase over the four years of 75,066, or 11 per cent. During the same period the number of medical certificates issued increased from 1,117,471 to 1,251,185. On the other hand, there was a steady growth in the number of insured persons and of the contributions paid by employers and employees. The contributions paid had increased from £509,500 in 1927 to £565,000 in 1930, an increase of 10.8 per cent. Sir James Craig (Dublin University), Dr. O'Dowd (Roscommon), Dr. Tubridy (Galway), and Dr. T. Hennessy (Dublin S.) took part in the discussion, and referred to the charges of lax certification and additional medical benefits for insured persons. In reply the Minister said that the weakness in medical certification was probably not due to the doctors. The difficulty was the indecision of doctors to put a person who had been in receipt of benefit back on the working list, but their certification of persons for two or three days had a material effect on the total amount of benefit to be paid.

Memorial to Dr. Arthur Dobbs, Athlone

Under the auspices of the Athlone branch of the District Nursing Association, a nurses' home, erected to the memory of the late Dr. Arthur Dobbs, medical officer of health for Athlone and district for thirty-eight years, and else[illegible] was opened recently by Mrs. Homan Mulock, Bellair House, Ballycumber. At a public meeting held after the ceremony the Very Rev. Canon Crowe remarked that the provision of a comfortable home for the district nurse was the best guarantee for the continuance of the association. He congratulated all those who had contributed to the success of the enterprise, especially Mr. Burgess, founder of the local nursing association, and Mrs. Murtagh, secretary of the home, whose enthusiasm and devotion had been invaluable. Miss Colburn, superintendent of Jubilee Nurses of Ireland, said that there were nearly two hundred district nursing associations in the country, but many more nurses were needed. No one could assert that their nurses were overpaid, in view of the very high qualifications demanded of them. In regard to the pension fund for nurses, half the sum required to ensure a pension for every nurse in Ireland had been obtained; there was still, however, a deficiency of £10,000. Last year the owners of private gardens had raised £4,000 by charging visitors a small fee for admission. She hoped that these garden schemes, which were organized for the benefit of the association and of the pension fund, would be extended. Dr. H. O'Neill, county medical officer, Westmeath, pleaded for the foundation of associations in other parts of the county. A voluntary association, he said, apart from stimulating interest in health, could give great assistance in carrying out the special services concerned with maternity, child welfare, and school medical inspection. He wondered sometimes if they appreciated sufficiently their good fortune in having a supply of nurses from the Institute of District Nursing in Dublin. These nurses were not only qualified in medical and surgical nursing, but they were certified midwives, capable of advising expectant and nursing mothers, and trained to deal with the minor ailments of infants and young children. Above all, they were able to recognize when medical advice was necessary. In paying a warm tribute to the work of the late Dr. Dobbs, Dr. O'Higgins praised the magnanimous spirit of self-sacrifice and devotion that was consistently shown by district nurses in extremely arduous circumstances.

Armagh Mental Hospital

Dr. Dora Allman has been appointed resident medical superintendent of Armagh Mental Hospital, at a salary of £600 a year and emoluments valued at £150 a year. Dr. Allman has been assistant medical officer in the institution for thirty-two years. She is the first woman to be appointed to such a post in Ireland.

England and Wales

Pay-Bed Section, Royal Victoria Infirmary, Newcastle

The Royal Victoria Infirmary, Newcastle-upon-Tyne, has issued a descriptive pamphlet outlining the features of its pay-bed section, which has been opened to provide up-to-date hospital treatment for patients of moderate means. In order to save the time and expense of multiple consultations, the medical services, which are supplied by the visiting and consulting staff of the infirmary, have been organized as in the wards of a large general hospital, a single inclusive fee being charged at a substantially reduced contract rate. This team service is stated to be complete in all branches of diagnosis and treatment, and a resident medical staff is available as required. The paying patients occupy three pavilions running north and south, with a total accommodation at present of eighty-six beds. Balconies, which can be enclosed by collapsible fronts glazed with "vita" glass, look out on to airing courts between the pavilions. Each of these three wings has clothing and food stores, clinical laboratory, sister's room, ward kitchen, interview room, linen room, and necessary staff offices. The buildings have been fitted up on approved modern principles with entirely new equipment. Single bedrooms contain a wash basin with hot and cold water, mirror, wardrobe, side table, bedside lamp, and a wireless apparatus. Other features include electrocardiograph leads to each pavilion; a fully equipped dark room for eye,

throat, ear, and nose cases; a sterilizing room, centrally situated; and two anaesthetic rooms. There are two main operating theatres with furniture and instruments of the latest type. The pamphlet is illustrated, and contains a list of regulations giving definite information about the conditions and cost of treatment. Patients are admitted only on the recommendation of a medical practitioner; for the assessment of fees for maintenance and medical services they are graded in four classes according to their income. No provision is made for maternity cases.

The Middlesex Hospital and Cancer Wing

Prince Arthur of Connaught, chairman of the board of management, presented, on April 15th, his report for 1930 on the Middlesex Hospital and Cancer Wing. His Royal Highness said that since the last report the reconstruction scheme had been carried a stage further. Additional out-patient accommodation and certain special wards had been built, and there now remained two big pieces of construction before the original reconstruction scheme could be completed. For the first, the Woolavington paying patients' block, they had money in hand, but for the completion of the second approximately £245,000 must be found. To accomplish this task would necessitate the concerted efforts of everyone interested in the Middlesex Hospital. The new buildings occupied last year were the out-patient department in the annexe, the neurological and observation wards, the Bernhard Baron children's ward, and the new residents' house. The total bed capacity of the hospital, including the cancer wing beds, was 471; and during the year 6,751 in-patients had been admitted, the average cost of each patient per week being £5 4s. 1d., and the average stay 22.49 days. The number of new out-patients was 52,118. Although the expenditure for the year had increased, amounting to £129,966, they were left with a balance of £11,635, chiefly as a consequence of legacies. On the advice of the medical committee and the cancer and general research committee, a new department of clinical research in radium therapy had been set up in order to correlate the results of work done on cancer at home and abroad. By this means reduplication of inquiry would be avoided, and the whole body of knowledge of this disease would be available for all those concerned in its investigation. The hospital had received a further loan of 370 mg. of radium, and an increase in the annual grant from the British Empire Campaign. At the convalescent home at Clacton, 1,460 patients had been treated in the past year; and the provision of an efficient nursing staff had made it possible to transfer patients in the early stages of recovery. This had enabled the hospital to meet growing demands for in-patient treatment. There had been a considerable increase in the work done in the infant welfare department. The hospital provided thirty-one resident appointments, and ten registrarships in medicine and surgery, which enabled men to work for three years at an adequate salary in the higher branches of their profession.

Mental Deficiency in London

The Mental Hospitals Committee of the London County Council has expressed its general agreement with the report of the Departmental Committee on Mental Deficiency (the "Wood" Report), and states that the main reason why so far there has not been an exhaustive overhaul of the patients in the London county mental hospitals, with a view to action under the Mental Deficiency Acts, has been the practical one that suitable accommodation in institutions for defectives has not been available to a sufficient extent to make such an overhaul worth while. Now that the Metropolitan Asylums Board's mental hospitals are coming under the Council's direction, and a "comb-out" of the Poor Law institutions is expected, it seems advisable that the population of the Council's mental hospitals should be subjected to an adequate review, and instructions have been given to that effect. With regard to the conclusion of the Departmental Committee, from figures submitted, that the number of defectives ascertained and provided for by local education and mental deficiency authorities is far smaller than it should be, the Mental Hospitals Committee strongly expresses the view that in London all that the law provides has as far as possible been done. It is also of opinion that the co-operation between the mental deficiency authority and other agencies exists in London to a degree as great as circumstances permit. Another suggestion from the Mental Hospitals Committee is that the recommendation of the Departmental Committee that defectives with incorrigible criminal tendencies and those suffering from a multiplicity of defect should be accommodated in institutions to be provided by the Board of Control ought not to be applied too rigidly in London so far as the "incorrigible" are concerned. At Farmfield, an L.C.C. institution where many of these defectives are placed, many apparently incorrigible lads have begun to amend. The Mental Hospitals Committee feels that the transfer of this institution to State control would hinder rather than help the problem of institutional care of defectives in London.

West London Hospital and the "Class Between"

A festival dinner was held in the Guildhall on May 12th to mark the seventy-fifth anniversary of the West London Hospital's existence, and also to make an appeal for funds on behalf of a scheme to solve the problem of the middle-class patient, as well as to improve the ordinary accommodation. Prince Arthur of Connaught, the president of the hospital, explained the purposes of the extension, already outlined in these pages (February 7th, p. 236). His Royal Highness said that for the past six years the hospital had provided accommodation in private rooms for twenty-six middle-class patients; and it had now been decided to add a further seventy-four private rooms, making 100 in all. Hitherto £5 5s. weekly had been charged for a private room, but this had been subject to additions varying in amount for medical and surgical fees and the cost of special treatments. Owing to the generosity and kindness of the honorary medical and surgical staff, to whom most grateful thanks were due for their valuable co-operation, a plan had been evolved for a flat-rate weekly payment, beginning at £7 7s. and increasing according to the patient's ability to pay. This fee would be inclusive, so that the patient would know in advance his periodical liability. He believed that this scheme had never been tried in England before, and that it was a great step forward in dealing with middle-class patients who could not afford the charges in nursing homes and the fees of private specialists. The hospital was also improving its ordinary wards, and remodelling its main frontage to make larger provision for the ever-increasing number of casualties, for the pathological laboratories, and for the *x*-ray and electrical departments. Mr. Winston Churchill, who was the principal guest, said that the community had had many burdens to face of recent years, but it had steadily maintained its system of help for the suffering. A very large part of our population was now provided for under the National Health Insurance Acts and other social legislation. At the opening of the present century, though there was much voluntary provision, there was no State provision; but the last twenty years had seen a system of insurance—contributory certainly, but also State-aided—come into being to deal, if not adequately, at least more comprehensively than in any other country with sickness and disease among great

masses of the people. Mr. Churchill believed that British social institutions had played a great part in mitigating the rancour of industrial disputes, in enabling the nation to emerge at least as well as any other from the stress of the war, and in making this country, in spite of everything, the best in which duke or dustman could live. These provisions for the wage-earning population, however, left untouched the black-coated man, the member of the upper section of the middle class, of the intelligentsia, which was essential to the life of the nation. He therefore commended the effort made by the West London Hospital, within the limits of its own organization, to fill the gap and meet a crying need.

Correspondence

THE NEW ZEALAND EARTHQUAKE

SIR,—The account of the New Zealand earthquake in your issue of May 16th is most interesting, and must have filled all your readers with pride at the action of Dr. Biggs and his staff. The manner in which they dealt with an unprecedented situation was worthy of the best traditions of British pluck, and I am sure every one of us, your readers, is proud of his profession and of that of the nurses. All showed not only great courage and determination, but also skill and ability in coping with the very difficult position in which they found themselves. I think we should all like Dr. Biggs and those associated with him to know how much we appreciate their remarkable achievement.—I am, etc.,

Hove, May 18th. L. A. PARRY.

OBSTETRIC SHOCK

SIR,—It may be hoped that Dr. Phillips's most valuable paper in the *Journal* of May 16th (p. 833) will draw attention, not only to the importance of emotional shock in bringing about obstetric shock, but to that of preparturient psychological situations in modifying the course and event of parturition and the puerperium. It is "not enough," however, to recognize that anxiety, worry, and so forth are "contributing causes" or "play an important part" in the bringing about of untoward happenings. Every general practitioner knows, or should know, as much as that.

Modern psychology, it should be clearly understood, has made real progress in analysing, classifying, or "typing" the kinds of situation that tend to be followed by certain kinds of reaction. So much is this the case that a physician who is not altogether unacquainted with certain modern psychological trends may, not without justification, be sometimes a little impatient when an illness, evidently to him expressive of a patient's mood, is considered by a colleague to have an explanation in terms of biochemistry, or even of endocrinology. Whatever we may think of Dickens as a portrayer of character, probably no writer of fiction—not even Guy de Maupassant—has ever been a finer observer of life situations than he; and, in the opening chapter of *Dombey and Son*, he has given us an imperishable record of the kind of way in which the first Mrs. Dombeys of the Victorian world "reacted" to the marital situations created for them by the Dombeys themselves—a race not yet extinct. Such deathbeds as those of the first Mrs. Dombey are perhaps rarer than they were, even thirty or forty years ago. But they still may be witnessed, and strong-minded Lousas still urge the patients to "make an effort," just as hearty young doctors from our athletic hospitals think they are practising psychology when adjuring their dying invalids to "buck up."

Dickens, indeed, affords us very many obstetrico-psychological pictures of the highest import—the death of the mother of David Copperfield is one of much the same type as the death of Mrs. Dombey. And there are other vignettes no less valuable. The Royal College of Physicians several years ago ceased to require—as some think, unfortunately—any evidence of even nominal acquaintance with the great sources of humane, as distinguished from scientific, knowledge, at the hands of candidates for membership. But we have now a College of Obstetricians and Gynaecologists, and perhaps that learned body might do worse than test the humanities of its young men by examining them in the works of Dickens, and calling for commentary on selected passages!

Sir John Rose Bradford has just impressively reminded us that our medical studies must not be confined to the laboratory; but even clinical or bedside study, in addition, is "not enough." Human medicine, which embraces psychology no less firmly than it does biochemistry and post-mortem research, cannot be learned unless studies are pursued in the market-place, or even, as Sydenham well knew, in the window-seat of a tavern. The best and truest of modern psychologies has been so learned. But the extent to which it has developed and to which it is applicable at the bedside and in the lying-in wards seems to be almost unknown to those who still hope to discover the secrets of life in the deadhouse.—I am, etc.,

London, W.1, May 16th. F. G. CROOKSHANK.

DETACHED RETINA

SIR,—Now that the so-called "Gonin's operation" for detachment of the retina is being done all over the British Isles, and, one may say, wherever ophthalmic surgery is done, I feel that it is of great importance that medical men should realize what a benefit it is if cases of detached retina are sent immediately to the nearest ophthalmic hospital or ophthalmic surgeon. I feel that I cannot do better than quote a small part of the latest paper written on Gonin's operation by Dr. Mark Amsler of Lausanne, in the *Klinische Monatsblätter für Augenheilkunde*, (January, 1931, vol. 86).

"But the indications will become more and more extended, and the prognosis of the operation will be better and better, if the patients start treatment as soon as possible under an ophthalmic surgeon—a knowledge which must become extended among the public, exactly like the conviction that only the immediate operation in acute appendicitis, with the fear of perforation, or in extrauterine pregnancy, can save life.

"In this sense medical men and patients must come to an understanding, and under this condition Gonin's thought will develop into a general beneficent act of healing, whose final form, without doubt, is not yet discovered; rather more, it will be further perfected in method and technique by all ophthalmologists."

—I am, etc.,

London, W.1, May 13th. J. COLE MARSHALL.

FRACTURES OF THE LONG BONES

SIR,—I have read with great interest Mr. Fagge's letter, in which he states that my reading of his remarks on the treatment of supracondylar fracture of the humerus was wrong, and that my interpretation of his writing was exactly the opposite of what was intended, and of what the words conveyed. In these circumstances I must at once apologize to Mr. Fagge, but I can assure him that, although a re-reading of the article now makes the meaning clear, I am by no means the only reader who obtained the wrong impression. His letter, however, raises interesting issues which will repay consideration, and I feel certain we may profitably study it with care in an effort at least to clear up some of the points of importance.

Mr. Fagge tells us that he can recall only one case of ischaemic contracture in his ward during the last ten years. This is stated to have been put up at once in full flexion—probably following on a fracture. This may well have been so, but can Mr. Fagge recollect sufficiently clearly after this interval, or can he get from his notes or his *x*-ray photographs the very important point as to whether or not the fracture was completely reduced? Similarly, in regard to the half-dozen cases he has seen at Examinations, he states that in none does it appear that malposition—that is, failure of reduction—is a marked feature. Surely this is not the point. Can Mr. Fagge state that in any one of these cases there was a complete reduction of the fracture? It is because supracondylar fractures of the humerus are generally oblique that the rectangular position of the elbow will not retain reduction. Many experiments have been carried out on this matter, but perhaps the fullest series are those reported by Ashhurst in his *Anatomical and Surgical Study of Fractures of the Lower End of the Humerus*. Here we find that a very lengthy and careful series of experiments confirms the clinical findings of surgeons generally that the fuller flexion of the elbow after reduction of a supracondylar fracture is the ideal position of retention. In this position of flexion the coronoid process of the ulna comes into the coronoid fossa, and effectually steadies the lower fragment on its anterior aspect, whilst the tense triceps tendon, lying closely against the posterior aspect of the shaft and fragment, acts as an efficient splint and retains the fragment in position—just as the tense capsule of the hip-joint retains the fractured neck of a femur in alignment when the hip has been placed in a position of abduction and internal rotation. Splints are undesirable in the treatment of a supracondylar fracture, necessitating as they do circular compression, and neither are they any more effective than the right-angled position in preventing lateral movement.

When Mr. Fagge goes so far as to say that after accurate reduction of the fracture it does not matter whether the elbow be fixed at an angle of 30 degrees, 90 degrees, *or more* (the italics are mine), I feel that his advice is positively harmful, because the ordinary oblique supracondylar fracture of the humerus cannot, and does not, stay reduced when put up in this last position.

In the concluding paragraph of his letter Mr. Fagge suggests that I should in future examine and report upon the stability of the elbow, both at an angle of 30 degrees and of 90 degrees, under the *x*-ray screen. This I have often done, and can assure him that the stability is much more marked in the more flexed than in the rectangular position. I would suggest, however, that the movement he advises—namely, that of flexion and extension—is but a very poor test. The movement that matters is backward and lateral displacement of the forearm. If this, which is obviously the only true test, is made, Mr. Fagge will no longer advocate the rectangular fixation.—I am, etc.,

T. P. McMURRAY.

Liverpool, May 18th.

FRACTURES OF THE NECK OF THE FEMUR

SIR,—The excellent article by Sir Robert Jones on fractures of the neck of the femur, published in the *Journal* of May 9th (p. 781), must surely convey a new optimism to many who have previously regarded such fractures in the aged with undue hopelessness. A favourable prognosis in 75 per cent. of all cases is a very different result from the high mortality rate which resulted from the old sand-bag method.

I have at present under my care an old lady, aged 84, who slipped and fell on the floor on September 3rd, 1930, sustaining a fracture of the neck of the left femur. Although no *x* rays were available, all the typical signs of a fractured neck were present—namely, adduction, shortening, external rotation, and loss of power. She refused to go to hospital, so extension was applied, the limb abducted and the foot internally rotated. Unfortunately the old lady would not tolerate this position for more than a week, and owing to her refusal to take any nourishment while so "trussed up," the bandages had all to be removed, and only extension could be maintained. Result—an un-united fracture with adduction and external rotation, but a healthy return of appetite at once.

On the morning of April 3rd, I received an urgent call to see her again. She had tried to get out of bed herself and had fallen and hurt her other thigh. On examination I found that she had a fracture of the right femur at the junction of the lower and middle thirds. This was reduced and fixed in plaster, an operation to which she submitted with very bad grace. She had recovered her appetite again in three days, but could not resist trying to get the plaster off. At the end of four weeks she had so loosened the plaster case that it had become useless, and on removing it I found that the fragments were well united. She refused to allow me to apply another plaster case, the best I could do being to apply lateral splints and maintain them in position with elastoplast bandages.

It seems now that if the old lady will allow me to try to correct the adduction of the left leg, the application of a walking calliper splint may enable her to leave her bed and resume her place as a comparatively active member of the family.—I am, etc.,

J. E. T SHIRLAW.

Upholland, May 13th.

SIR,—With reference to Sir Robert Jones's article on fractures of the neck of the femur in your issue of May 9th, I note that in two places (p. 782, col. 1, under "Diagnosis," and p. 783, col. 2, under "The old un-united case") the signs and deformities typical of a fracture in this situation are described respectively as (*a*) *adduction*, shortening, and external rotation, and (*b*) ". . . flexion of the thigh, *adduction*, rotation outwards . . ." I have always been taught that the classical signs of a fracture of the neck of the femur are shortening, *abduction*, and eversion of the limb on the affected side. I should therefore be grateful if this apparently divergent view—if I have read the article correctly—could be elucidated.—I am, etc.,

C. S.

London, May 11th.

CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION, WITH GLYCOSURIA

SIR,—The letters of Dr. Cruickshank and Dr. Tytler Burke on this subject are interesting, because they represent two schools of thought which are bound to come into conflict before long. Dr. Burke rightly attributes the syndrome to syphilitic infection because he can demonstrate microscopically every step in its development. Dr. Cruickshank deplores this inclination to blame the *Treponema pallidum* for the lesions while other etiological factors are apt to be ignored. He mentions two—alcohol and tobacco—and syphilologists have a right to ask him to demonstrate microscopically the steps from poisoning with alcohol or tobacco to fully developed coronary thrombosis. When he does this he can claim for alcohol and tobacco the same well-founded position in the etiology as is enjoyed by syphilis.

Medical students are still taught, and their teachers must be assumed to believe, that alcohol, lead, syphilis, and gout are equally responsible for a mass of indefinite chronic degenerations. This is a Victorian tradition, born in an age too respectable to believe that a "filth" disease could possibly be responsible for many of its

masses of the people. Mr. Churchill believed that British social institutions had played a great part in mitigating the rancour of industrial disputes, in enabling the nation to emerge at least as well as any other from the stress of the war, and in making this country, in spite of everything, the best in which duke or dustman could live. These provisions for the wage-earning population, however, left untouched the black-coated man, the member of the upper section of the middle class, of the intelligentsia, which was essential to the life of the nation. He therefore commended the effort made by the West London Hospital, within the limits of its own organization, to fill the gap and meet a crying need.

Correspondence

THE NEW ZEALAND EARTHQUAKE

SIR,—The account of the New Zealand earthquake in your issue of May 16th is most interesting, and must have filled all your readers with pride at the action of Dr. Biggs and his staff. The manner in which they dealt with an unprecedented situation was worthy of the best traditions of British pluck, and I am sure every one of us, your readers, is proud of his profession and of that of the nurses. All showed not only great courage and determination, but also skill and ability in coping with the very difficult position in which they found themselves. I think we should all like Dr. Biggs and those associated with him to know how much we appreciate their remarkable achievement.—I am, etc.,

Hove, May 18th. L. A. PARRY.

OBSTETRIC SHOCK

SIR,—It may be hoped that Dr. Phillips's most valuable paper in the *Journal* of May 16th (p. 833) will draw attention, not only to the importance of emotional shock in bringing about obstetric shock, but to that of preparturient psychological situations in modifying the course and event of parturition and the puerperium. It is "not enough," however, to recognize that anxiety, worry, and so forth are "contributing causes" or "play an important part" in the bringing about of untoward happenings. Every general practitioner knows, or should know, as much as that.

Modern psychology, it should be clearly understood, has made real progress in analysing, classifying, or "typing" the kinds of situation that tend to be followed by certain kinds of reaction. So much is this the case that a physician who is not altogether unacquainted with certain modern psychological trends may, not without justification, be sometimes a little impatient when an illness, evidently to him expressive of a patient's mood, is considered by a colleague to have an explanation in terms of biochemistry, or even of endocrinology. Whatever we may think of Dickens as a portrayer of character, probably no writer of fiction—not even Guy de Maupassant—has ever been a finer observer of life situations than he; and, in the opening chapter of *Dombey and Son*, he has given us an imperishable record of the kind of way in which the first Mrs. Dombeys of the Victorian world "reacted" to the marital situations created for them by the Dombeys themselves—a race not yet extinct. Such deathbeds as those of the first Mrs. Dombey are perhaps rarer than they were, even thirty or forty years ago. But they still may be witnessed, and strong-minded Lousas still urge the patients to "make an effort," just as hearty young doctors from our athletic hospitals think they are practising psychology when adjuring their dying invalids to "buck up."

Dickens, indeed, affords us very many obstetrico-psychological pictures of the highest import—the death of the mother of David Copperfield is one of much the same type as the death of Mrs. Dombey. And there are other vignettes no less valuable. The Royal College of Physicians several years ago ceased to require—as some think, unfortunately—any evidence of even nominal acquaintance with the great sources of humane, as distinguished from scientific, knowledge, at the hands of candidates for membership. But we have now a College of Obstetricians and Gynaecologists, and perhaps that learned body might do worse than test the humanities of its young men by examining them in the works of Dickens, and calling for commentary on selected passages!

Sir John Rose Bradford has just impressively reminded us that our medical studies must not be confined to the laboratory; but even clinical or bedside study, in addition, is "not enough." Human medicine, which embraces psychology no less firmly than it does biochemistry and post-mortem research, cannot be learned unless studies are pursued in the market-place, or even, as Sydenham well knew, in the window-seat of a tavern. The best and truest of modern psychologies has been so learned. But the extent to which it has developed and to which it is applicable at the bedside and in the lying-in wards seems to be almost unknown to those who still hope to discover the secrets of life in the deadhouse.—I am, etc.,

London, W.1, May 16th. F. G. CROOKSHANK.

DETACHED RETINA

SIR,—Now that the so-called "Gonin's operation" for detachment of the retina is being done all over the British Isles, and, one may say, wherever ophthalmic surgery is done, I feel that it is of great importance that medical men should realize what a benefit it is if cases of detached retina are sent immediately to the nearest ophthalmic hospital or ophthalmic surgeon. I feel that I cannot do better than quote a small part of the latest paper written on Gonin's operation by Dr. Mark Amsler of Lausanne, in the *Klinische Monatsblätter für Augenheilkunde*, (January, 1931, vol. 86).

"But the indications will become more and more extended, and the prognosis of the operation will be better and better, if the patients start treatment as soon as possible under an ophthalmic surgeon—a knowledge which must become extended among the public, exactly like the conviction that only the immediate operation in acute appendicitis, with the fear of perforation, or in extrauterine pregnancy, can save life.

"In this sense medical men and patients must come to an understanding, and under this condition Gonin's thought will develop into a general beneficent act of healing, whose final form, without doubt, is not yet discovered; rather more, it will be further perfected in method and technique by all ophthalmologists."

—I am, etc.,

London, W.1, May 13th. J. COLE MARSHALL.

FRACTURES OF THE LONG BONES

SIR,—I have read with great interest Mr. Fagge's letter, in which he states that my reading of his remarks on the treatment of supracondylar fracture of the humerus was wrong, and that my interpretation of his writing was exactly the opposite of what was intended, and of what the words conveyed. In these circumstances I must at once apologize to Mr. Fagge, but I can assure him that, although a re-reading of the article now makes the meaning clear, I am by no means the only reader who obtained the wrong impression. His letter, however, raises interesting issues which will repay consideration, and I feel certain we may profitably study it with care in an effort at least to clear up some of the points of importance.

Mr. Fagge tells us that he can recall only one case of ischaemic contracture in his ward during the last ten years. This is stated to have been put up at once in full flexion—probably following on a fracture. This may well have been so, but can Mr. Fagge recollect sufficiently clearly after this interval, or can he get from his notes or his *x*-ray photographs the very important point as to whether or not the fracture was completely reduced? Similarly, in regard to the half-dozen cases he has seen at Examinations, he states that in none does it appear that malposition—that is, failure of reduction—is a marked feature. Surely this is not the point. Can Mr. Fagge state that in any one of these cases there was a complete reduction of the fracture? It is because supracondylar fractures of the humerus are generally oblique that the rectangular position of the elbow will not retain reduction. Many experiments have been carried out on this matter, but perhaps the fullest series are those reported by Ashhurst in his *Anatomical and Surgical Study of Fractures of the Lower End of the Humerus*. Here we find that a very lengthy and careful series of experiments confirms the clinical findings of surgeons generally that the fuller flexion of the elbow after reduction of a supracondylar fracture is the ideal position of retention. In this position of flexion the coronoid process of the ulna comes into the coronoid fossa, and effectually steadies the lower fragment on its anterior aspect, whilst the tense triceps tendon, lying closely against the posterior aspect of the shaft and fragment, acts as an efficient splint and retains the fragment in position—just as the tense capsule of the hip-joint retains the fractured neck of a femur in alignment when the hip has been placed in a position of abduction and internal rotation. Splints are undesirable in the treatment of a supracondylar fracture, necessitating as they do circular compression, and neither are they any more effective than the right-angled position in preventing lateral movement.

When Mr. Fagge goes so far as to say that after accurate reduction of the fracture it does not matter whether the elbow be fixed at an angle of 30 degrees, 90 degrees, *or more* (the italics are mine), I feel that his advice is positively harmful, because the ordinary oblique supracondylar fracture of the humerus cannot, and does not, stay reduced when put up in this last position.

In the concluding paragraph of his letter Mr. Fagge suggests that I should in future examine and report upon the stability of the elbow, both at an angle of 30 degrees and of 90 degrees, under the *x*-ray screen. This I have often done, and can assure him that the stability is much more marked in the more flexed than in the rectangular position. I would suggest, however, that the movement he advises—namely, that of flexion and extension—is but a very poor test. The movement that matters is backward and lateral displacement of the forearm. If this, which is obviously the only true test, is made, Mr. Fagge will no longer advocate the rectangular fixation.—I am, etc.,

Liverpool, May 18th. T. P. McMURRAY.

FRACTURES OF THE NECK OF THE FEMUR

SIR,—The excellent article by Sir Robert Jones on fractures of the neck of the femur, published in the *Journal* of May 9th (p. 781), must surely convey a new optimism to many who have previously regarded such fractures in the aged with undue hopelessness. A favourable prognosis in 75 per cent. of all cases is a very different result from the high mortality rate which resulted from the old sand-bag method.

I have at present under my care an old lady, aged 84, who slipped and fell on the floor on September 3rd, 1930, sustaining a fracture of the neck of the left femur. Although no *x* rays were available, all the typical signs of a fractured neck were present—namely, adduction, shortening, external rotation, and loss of power. She refused to go to hospital, so extension was applied, the limb abducted and the foot internally rotated. Unfortunately the old lady would not tolerate this position for more than a week, and owing to her refusal to take any nourishment while so "trussed up," the bandages had all to be removed, and only extension could be maintained. Result—an un-united fracture with adduction and external rotation, but a healthy return of appetite at once.

On the morning of April 3rd, I received an urgent call to see her again. She had tried to get out of bed herself and had fallen and hurt her other thigh. On examination I found that she had a fracture of the right femur at the junction of the lower and middle thirds. This was reduced and fixed in plaster, an operation to which she submitted with very bad grace. She had recovered her appetite again in three days, but could not resist trying to get the plaster off. At the end of four weeks she had so loosened the plaster case that it had become useless, and on removing it I found that the fragments were well united. She refused to allow me to apply another plaster case, the best I could do being to apply lateral splints and maintain them in position with elastoplast bandages.

It seems now that if the old lady will allow me to try to correct the adduction of the left leg, the application of a walking calliper splint may enable her to leave her bed and resume her place as a comparatively active member of the family.—I am, etc.,

Upholland, May 13th. J. E. T. SHIRLAW.

SIR,—With reference to Sir Robert Jones's article on fractures of the neck of the femur in your issue of May 9th, I note that in two places (p. 782, col. 1, under "Diagnosis," and p. 783, col. 2, under "The old un-united case") the signs and deformities typical of a fracture in this situation are described respectively as (*a*) *adduction*, shortening, and external rotation, and (*b*) ". . . flexion of the thigh, *adduction*, rotation outwards . . ." I have always been taught that the classical signs of a fracture of the neck of the femur are shortening, *abduction*, and eversion of the limb on the affected side. I should therefore be grateful if this apparently divergent view—if I have read the article correctly—could be elucidated.—I am, etc.,

CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION, WITH GLYCOSURIA

SIR,—The letters of Dr. *Cruickshank* and Dr. Tytler Burke on this subject are interesting, because they represent two schools of thought which are bound to come into conflict before long. Dr. Burke rightly attributes the syndrome to syphilitic infection because he can demonstrate microscopically every step in its development. Dr. Cruickshank deplores this inclination to blame the *Treponema pallidum* for the lesions while other etiological factors are apt to be ignored. He mentions two—alcohol and tobacco—and syphilologists have a right to ask him to demonstrate microscopically the steps from poisoning with alcohol or tobacco to fully developed coronary thrombosis. When he does this he can claim for alcohol and tobacco the same well-founded position in the etiology as is enjoyed by syphilis.

Medical students are still taught, and their teachers must be assumed to believe, that alcohol, lead, syphilis, and gout are equally responsible for a mass of indefinite chronic degenerations. This is a Victorian tradition, born in an age too respectable to believe that a "filth" disease could possibly be responsible for many of its

woes. When Dr. Cruickshank joins Dr. Hurst in deploring the tendency to fall back on syphilis in any diagnostic uncertainty, he forgets that the uncertainty is an attribute of alcohol, tobacco, lead, etc., and that nothing is more certain or better established in medicine than the microscopical pathology of syphilis.—I am, etc.,

GRIFFITH EVANS.

Carnarvon, May 17th.

A BARBER-SURGEON'S INSTRUMENT CASE

SIR,—The sixteenth century case for surgical instruments, so well described by Mr. C. J. S. Thompson in your issue of May 9th (p. 811), ought surely to be preserved in the Museum of the Royal College of Surgeons in Lincoln's Inn Fields, for it is the gift of a king to an English surgeon. The price at which it would be sold is easily ascertainable, and if this were reasonable every effort ought to be made to buy it. I would for my own part gladly subscribe five guineas towards a fund for the purpose.—I am, etc.,

D'ARCY POWER.

London, W., May 18th.

SPINAL ANAESTHESIA

SIR,—I should like to add my thanks to Mr. A. Wilfrid Adams for his contribution on spinocain, published in the *Journal* of May 9th (p. 785). As a result of a chance communication with Professor Burgess of Manchester some time ago, I have used spinocain in some hundreds of cases at the two hospitals in Bradford, and I can endorse almost entirely the conclusions arrived at by Mr. Adams. I have, however, despite various trials with body tilt, been unable with the 2 c.cm. ampoule of spinocain to obtain satisfactory anaesthesia and relaxation for abdominal operations in the region of the diaphragm. On inquiry I find this is the experience of others. I also learn that Pitkin himself finds a bigger quantity (3 c.cm.) necessary for such high operations. If this is true, and 3 c.cm. can be safely given with a suitable body tilt, it is a very important addition to our knowledge. I should like to know the experience of others on this point.

An important complication mentioned by Mr. Adams has interested me—namely, temporary paralysis of the external rectus muscle of the eye. This has happened in two of my "spinocain cases" operated on for acute appendicitis; they both had occupied the same bed in the hospital, which made us think of external causes, and each took four weeks to recover.—I am, etc.,

BASIL HUGHES.

Bradford, May 12th.

SCHISTOSOME WORMS AND SCHISTOSOME MONSTERS

SIR,—In suggesting, in your issue of May 9th (p. 817), that Dr. M. Khalil, in his recent *Bibliography of Schistosomiasis*, is the first to err in classifying the papers of purely teratological interest by Eisenbarth and Notter as helminthological, Professor Leiper is perhaps a little unfair. Dr. Khalil has erred in good company. The reference to R. Eisenbarth's paper "Ein Fall von *Schistosoma reflexum*" (*Wochenschrift für Tierh. u. Viehzucht*) was given by those doyens of medical bibliography Drs. Robert Fletcher and Fielding H. Garrison under the heading "Diseases due to Parasites (Animal and Vegetable)" in the *Index Medicus* (1908, p. 720), and also appeared under the heading "Schistosomiasis [Katayama disease]" on page 205 of the *Index-Catalogue of the Library of the Surgeon-General's Office, U.S. Army*, (1910, second series, vol. xv).

C. Notter's paper "Schistosomen beim Schwein" (*Virchow's Arch. f. path. Anat.*) appeared with the translation "Schistosomiasis in pigs" under the heading "Schistosomiasis" on page 1125 of the *Quarterly Cumulative Index Medicus* (1927, vol. ii), issued under the joint auspices of the American Medical Association and the Surgeon-General's Library, and in *Biological Abstracts*, (1929, vol. iii, p. 1367), under the heading "Parasitology (Animal)."

Medical bibliography is beset with pitfalls. It would be hard if Dr. Khalil should be held entirely responsible for one that had been dug by others.—I am, etc.,

R. L. SHEPPARD.

St. John's Wood, N.W., May 11th.

ACIDOSIS AND SEBORRHOEA

SIR,—I was interested to read in your issue of May 16th (p. 839) that Drs. Ingram and Fowweather had been unable to find any evidence of the presence of acidosis in persons subject to seborrhoeic disorders, because I am able to confirm their findings in a few typical cases referred to me by Dr. H. W. Barber in 1923. Seven cases only were investigated, and in all the plasma bicarbonate, estimated by the method of Van Slyke, Stillman, and Cullen (*Journ. Biol. Chem.*, 1919, xxxvii, 167), was normal. The mean value obtained was 0.033 molar, the highest being 0.036 and the lowest 0.032 molar. All the cases were males. There was therefore no evidence of acidosis in this small series. The urine was not investigated, and I have no experience of the treatment of this condition.—I am, etc.,

A. ARNOLD OSMAN.

London, W., May 17th.

CANCER AND RACE

SIR,—Dr. M. Sorsby, whose book is reviewed in your issue of May 9th (p. 800), can certainly be congratulated on completion of a useful and original piece of work. But is he justified in his insistence on the importance of the Mosaic law of sexual hygiene? If that were so, then the *puella publica* would be the greatest sufferer from carcinoma of the uterus; but, as far as my knowledge goes, she is not. For every form of carcinoma, and in any part of the body, chronic irritation and trauma are the predisposing factors. Gonorrhoea was notoriously rare among the strictly orthodox Jews; with relaxation of the religious influence the Jewish communities show the same amount of sexual laxity as their Christian neighbours—hence the increase of gonorrhoea, with chronic cervicitis, endometritis, etc. I still remember the wise words of Fritsch, that "without gonorrhoea there would be no gynaecology." As a general formula it may be exaggerated, but there is a great deal of truth in it.—I am, etc.,

N. PINES.

London, E.1, May 11th.

IMMUNIZATION AGAINST VACCINIA

SIR,—We have to thank Dr. Bland for drawing our attention to an error in our paper published in your issue of May 2nd. In the last paragraph but one of the protocol, published on page 741, "Rabbit 118" should obviously read "Rabbit 119," and vice versa.—We are, etc.,

G. M. FINDLAY,
E. HINDLE.

Wellcome Bureau of Scientific Research, London, May 16th.

DIET AND THE TEETH

SIR,—In Part II of my report, "Diet and the teeth: an experimental study" (Medical Research Council Special Reports Series No. 153), I referred to a paper entitled "A histological investigation into so-called pyorrhoea alveolaris," published in the *British Dental Journal* of 1927. I regret that in giving the names of the authors I omitted to include that of Dr. Arthur Counsell, who collaborated with Mr. W. Warwick James.—I am, etc.,

MAY MELLANBY.

Sheffield, May 15th.

Medico-Legal

ETHER-OXYGEN ANAESTHETIC FATALITY

An inquest was held by the Birmingham coroner, on May 12th, on the body of a man, aged 60, who died in unusual circumstances at the General Hospital, Birmingham, on April 20th.

On April 15th, in the course of an operation for dilatation of a cancerous growth of the oesophagus with insertion of radium, and while the surgeon was withdrawing a small pencil light, an explosion occurred in the patient's mouth, and the Shipway apparatus delivering the anaesthetic exploded and burst into flames. The Shipway apparatus was connected to a cylinder of oxygen, and the gas was passed through it to a rubber tube inserted in the patient's nostril and fitted to an intratracheal catheter. Induction was by means of ether (1 part) and chloroform (2 parts) mixture—open method—and when the apparatus was first used a mixture of oxygen, chloroform, and ether was given, but at the time of the explosion and before the lamp was inserted into the mouth the apparatus was set to cut off all ether, and to deliver only chloroform and oxygen. It was admitted, however, that a small quantity of ether vapour may also have been passing to the patient. The pencil light was fitted with an ordinary commercial type Osram 3½-volt metal filament lamp, screwed into the lamp holder, and the lighting current was derived from a 4-volt accumulator situated outside the operating theatre and connected to the lamp by flex insulated wire over 20 feet in length.

Professor G. Haswell Wilson, who made a post-mortem examination, said that there was extensive bruising of the pharyngeal mucous membrane, especially round the rima glottidis. There was a ragged tear in the mucous membrane of the left pyriform fossa 3/4 inch in length, with underlying tissues infiltrated with pus. There were haemorrhages beneath the mucous membrane of the epiglottis. The mucous membrane of the trachea and larger bronchi was covered with a thin layer of fibrinous exudate and bathed in pus. The bronchi were intensely congested, containing a large amount of a foul-smelling pus. The substance of the lungs was oedematous, with some areas of early pneumonia towards the base. A cancerous growth was found behind the cricoid cartilage, 1¼ inches in length, encircling the lumen of the oesophagus, with marked narrowing. "The changes in the lung were those of intense inflammation of the bronchial tree, with decomposition of the inflammatory exudate. The fact that the inflammation of the bronchi was extreme while there was but little evidence of pneumonia suggested that the lung tissue had not been damaged to any extent in the first instance. From the history of the case it is probable that the mucous membrane of the trachea and the bronchi had been extensively damaged by heat with subsequent putrid bronchitis as a cause of death."

It was established that the explosion first occurred in the patient's mouth, and from there was transmitted along the rubber tube to the Shipway apparatus. The cause of the explosion was attributed to defective contact between the lamp and the holder, thus causing a spark. Experiments conducted by Dr. Morgan (who was a member of the committee to report on "risks associated with electric exploders in coal mines" to the Department of Mines) demonstrated that while a spark from a 4-volt accumulator failed to explode ether vapour mixed with air in explosive proportions (volume of ether 2.9 to 7.5, volume of air 97.1 to 92.5) an explosion readily occurred in mixtures of oxygen and ether. The current consumption of the lamp in use when full on was 0 3 ampere. A current of 0.25 ampere was sufficient to cause ignition readily, and his experiments led him to the conclusion that any spark, however small, must be regarded as highly dangerous in an ether-oxygen mixture.

ALLEGED FRAUDULENT MISREPRESENTATION BY MEDICAL ADVISER

In the King's Bench Division, before Mr. Justice Horridge and a special jury, on May 11th and four following days, the claim was heard of Mrs. Ada Ann Oliver of Hotel Somerset, London, W., against Dr. Ernest Snowden of New Cavendish Street, W., for damages for alleged negligence, alleged breach of duty as medical adviser, and alleged fraudulent misrepresentation. All the charges were denied.

Sir Patrick Hastings, K.C., who appeared for the plaintiff, said that Mrs. Oliver had suffered from a nervous complaint, and her general practitioner had advised her "to consult a psycho-analyst." Dr. Snowden, a psychologist, attended her from February, 1928, until the autumn of 1929. The fees for that period amounted to £1,350. Dr. Snowden was a director of a sulphur mining company which had been in suspended animation for some years, though apparently it hoped to acquire wealth from sulphur deposits in Nisiro, in the Eastern Mediterranean. Dr. Snowden told Mrs. Oliver of this company, stating that it was a new one, that it owned valuable sulphur mines, and was likely to pay large dividends. In July, 1928, he persuaded her to purchase 4,000 five shilling shares.

Mrs. Oliver, in evidence, said that she was instructed by Dr. Snowden as part of the treatment to tell him everything about herself. He always had the blind down so that she could better concentrate and subordinate her will to his. She told him that she had £3,000 or £4,000 on deposit, and when he described the prospects of the sulphur company she asked her husband to write the cheque for £1,000 (at that time she had been in bed for about nine months, and was unable to write a cheque herself). She had never received any part of the money back, or any dividend in respect of it, though she had asked Dr. Snowden "hundreds of times." In cross-examination, she said she was grateful to Dr. Snowden for his treatment, and had confidence in him until this occurrence. She admitted that on January 1st last she wrote begging Dr. Snowden (whom she had then not seen for fourteen months) to visit her, saying, "You cannot imagine the happiness it will bring me." She was a very sick woman, and felt that he could still help her with his psychological treatment. On her remarking that Dr. Snowden was a psychologist, not a psycho-analyst, the judge said that he did not know the difference, and Sir Patrick Hastings added, "I do not know which is the worse."

Mr. Doughty, K.C., for the defence, said that Dr. Snowden was practising with considerable success a serious branch of medical science, and the treatment of Mrs. Oliver had had very good results. He had talked to Mrs. Oliver about various matters to get her interested, and, discovering her interest in business affairs, he told her about the sulphur mining company. She said that she would like to invest. Realizing how undesirable it was that he should have anything to do with the financial affairs of a patient, he endeavoured to dissuade her, and, finding that impossible, suggested that she should invest no more than £200; but she insisted, and her husband, to whom he also appealed, said she was to do as she wanted. After the money had been paid, it was discovered that the owner of the concession in the Mediterranean was giving trouble, and the company was brought to a standstill, but Mrs. Oliver continued on friendly terms, and there was no suggestion of fraud until the writ was issued.

Dr. Snowden, in evidence, said that he was psychologist to the Hospital for Epilepsy and Paralysis, Maida Vale, and assistant in the psychological department, St. Bartholomew's. He did not practise as a psycho-analyst. Mrs. Oliver was suffering from acute anxiety and obsessional fears, of which he endeavoured to discover the original cause. It was no part of his treatment to discover the extent of her private banking account. In cross-examination, Dr. Snowden said that he became a director of the company in May, 1928, at which time it had no assets, but a series of agreements existed by which the company was to acquire concessions to work the sulphur mines in Nisiro. He was closely cross-examined on some of the proceedings of the company, and said that he knew nothing about business matters, and simply did what he was instructed or advised to do. He would not agree that at the time Mrs. Oliver paid the money she was in a serious mental condition, but it was necessary for him to attend every day, because, if he did not, she became anxious and worried. Corroborative evidence on certain points connected with the affairs of the company was given.

The jury returned a verdict for the defendant, but added the rider: "We desire to say we feel that the defendant was unwise in receiving from his patient money for a concern in which he was interested." Judgement was entered for Dr. Snowden on the claim, and also on a counterclaim of 72 guineas (fees for twenty-four visits), together with costs.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Registration and Regulation of Osteopathy Bill was withdrawn on May 12th, having failed to secure a second reading.

The House of Commons took the second reading of the Finance Bill this week, and also debated the Representation of the People Bill and the vote of the Foreign Office.

During the debate on the Finance Bill, on May 13th, Sir Stafford Cripps, Solicitor-General, said it was impossible to exempt from the land values tax land held by colleges and hospitals.

The Sentence of Death (Expectant Mothers) Bill was reported to the House of Commons with amendments from a committee on May 14th.

The second reading of the Pharmacy and Poisons Bill was set down by the Government for May 15th in the House of Commons, but the discussion on it was postponed by agreement. On the previous day a deputation of members, including Dr. Salter and Mr. Somerville Hastings, had met Mr. Short, Under Secretary for Home Affairs, to consider the suggestions made by the pharmacists for amending the Bill. The postponement of the Bill followed.

In the House of Commons, on May 18th, the London Squares Preservation Bill was read a second time.

The text of the Proprietary Medicines Bill was issued on May 18th, and is reproduced in the *Supplement* this week at page 203. This Bill does not apply to Scotland or Northern Ireland.

Miss Lawrence told Mr. Haydon Jones, on May 19th, that, owing to the state of business, the Government could not introduce legislation this session to give effect to the recommendations of the Select Committee on Patent Medicines, which was issued in 1914.

In the House of Lords, on May 19th, the Workmen's Compensation Bill was read a second time.

Lotteries for Hospitals

On May 19th Sir W. DAVISON asked leave to introduce the Hospitals Lotteries Bill, to authorize the raising of money by means of lotteries for the support of hospitals. He said that he had sent to the Home Secretary a memorial signed by seventy members of the House asking him to take this matter into consideration. He had also furnished Mr. Clynes with the results of a questionary recently sent out by the Special Appeals Committee of St. Bartholomew's Hospital to some thousands of representative people, including supporters of the hospital. The result to date was that 3,125 persons were stated to be in favour of a lottery for the hospital, and only 61 were against. Meanwhile nothing was being done, and British hospitals were in the greatest need of funds for building, equipment, and maintenance. He was aware that a number of members of the House of Commons considered that hospitals should be a charge upon the State, but even they must surely realize, in view of the statements of the Chancellor of the Exchequer in presenting his Budget, that it was not practical politics in present financial conditions to provide State money for hospitals in the immediate future. The chairman of a large hospital, in a letter to the *Times*, pointed out that hospitals were being seriously prejudiced by the uncertain state of the law in regard to this matter, and that they were losing subscriptions, both from those in favour of and from those opposed to lotteries. That supported the view that it was time this uncertainty of the law should be ended, at any rate so far as hospitals were concerned. Immense sums had been raised in Dublin in aid of the Southern Irish hospitals. The Bill did not attempt to modify or remove the many anomalies relating to lotteries, raffles, and sweepstakes. It was a short, permissive measure, which left the law as it stood until such time as the Government were in a position to deal with it. The Bill provided that, notwithstanding anything in the existing law, a lottery might be held under regulations to be approved by the Home Secretary for the benefit of British hospitals something on the lines of the Irish Free State hospitals lottery, but with improved regulations as a result of experience gained in the conduct of that lottery.

Mr. FOOT opposed the Bill, which, he said, could not be limited to hospitals. If a lottery was right for hospitals, it was right for the blind, for orphanages, and for every beneficent enterprise—national and municipal. This was a charity lottery which would not achieve its purpose, but would dry up the sources of charity. A short time ago the Earl of Onslow, at one time chairman of the Voluntary Hospitals Commission, wrote to the *Times* setting out his reasons for condemning this proposal as disastrous to the financial interests of the hospitals of this country. The same opinion was given by the chairman of the Royal London Ophthalmic Hospital, and by Sir Arthur Stanley, treasurer of St. Thomas's Hospital.

Leave to introduce the Bill was refused by 181 votes to 58.

Deaths from Cancer

On May 8th Mr. FREEMAN asked Mr. Greenwood the percentage increase or decrease in deaths from cancer each year since the Imperial Cancer Research Fund was started, taking the figures for the first year as a basis. On May 14th Mr. GREENWOOD replied that he could not answer the question in that precise form, but he could give the percentage increase which had been in the certificates of cause of deaths classified to cancer in England and Wales in each of the years from 1903 to 1930, compared with the number of deaths registered and so classified in the year 1902. The figures were: 1903, 4.37; 1904, 6.49; 1905, 8.43; 1906, 13.62; 1907, 13.90; 1908, 17.38; 1909, 22.18; 1910, 24.16; 1911, 28.81; 1912, 33.91; 1913, 39.71; 1914, 41.78; 1915, 42.96; 1916, 45.77; 1917, 47.67; 1918, 47.92; 1919, 51.21; 1920, 56.74; 1921, 65.12; 1922, 68.28; 1923, 74.61; 1924, 80.79; 1925, 86.35; 1926, 90.94; 1927, 94.02; 1928, 101.83; 1929, 104.13; 1930, 107.67 (based on provisional figures).

Milk

Answering Captain Peter Macdonald, on May 14th, Mr. GREENWOOD said that samples of imported dried and condensed milks were taken both at the time of importation and at the time of exposure for sale. These were examined by the Government chemists and the public analysts to ascertain whether the requirements of the regulations on composition and labelling were observed. These regulations required that if fat had been removed from the milk from which the dried or condensed milk is made the fact must be clearly declared on the label. If any constituent of natural milk, other than water or fat, were removed the product would not fall within the definition of dried or condensed milk. He saw no need for legislation on the subject.

In a further reply to Captain Macdonald, on May 14th, Mr. GREENWOOD said that in consultation with Dr. Addison he was considering the introduction of legislation to regulate the production and sale of milk with a view to reducing the incidence of bovine tuberculosis in human beings.

Answering Dr. Fremantle, on May 14th, Mr. GREENWOOD said the Ministry of Health memorandum on bovine tuberculosis in man had been published as a non-parliamentary paper, and was available to M.P.'s on application.

Animal Experiments.—On May 15th Mr. Freeman asked who, in experiments on living animals, decided whether the experiment was calculated to give pain; and if the performer was the only judge. Mr. CLYNES answered: In this Act, as in all others, people have to consider for themselves whether what they propose to do is in accordance with the law; but if they infringe the provisions of the Act they are liable to have legal proceedings taken against them, and the court decides whether the experiment is or is not calculated to cause pain. Experience shows that people who propose to perform experiments which might by any possibility be regarded as calculated to cause pain are anxious to comply with the requirements of the Act in order to be on the safe side.

Infant Mortality.—Mr. Greenwood reports that, according to the most recent available returns, which are those for 1926-30, Paddington, Stepney, and Shoreditch are the metropolitan boroughs with the highest infantile mortality rates.

Obituary

T. R. GLYNN, M.D., F.R.C.P.

Consulting Physician, Royal Infirmary, Liverpool; late Professor of Medicine, Liverpool University

As briefly recorded in last week's *Journal*, Emeritus Professor T. R. Glynn died on May 12th, at his residence, near St. Asaph, in North Wales. He was in his ninety-first year.

Thomas Robinson Glynn, son of Edward Dashper Glynn, a Liverpool shipowner, was educated at Liverpool College, and studied medicine at St. Bartholomew's Hospital and in Paris. He graduated M.B. at the University of London in 1865, taking the M.D. in 1879. Elected a Fellow of the Royal College of Physicians of London in 1882, he was appointed Lumleian Lecturer in 1903, Councillor in 1907-9, and Bradshaw Lecturer in 1913. He was president of the Liverpool Medical Institution in 1892 and 1893, and president of the Association of Physicians in 1910.

Soon after settling in Liverpool he was appointed assistant physician to the Children's Hospital, physician to the Northern Hospital, and in 1871 physician to the Royal Infirmary, passing on to the consulting staff in 1901, when he reached the retiring age. Other appointments were: chief medical officer to the Royal Insurance Company and examiner for others; medical officer to H.M. Customs, and for many years consulting physician to the Woolton Convalescent Hospital, the Hoylake Cottage Hospital, the Liverpool Dental Hospital, and physician to the Catholic Blind Asylum. Though he had bought a general practice, this work was soon given up, and a large and widely spread consulting practice in Lancashire, Cheshire, and North Wales was built up and held for fifty years.

Dr. Glynn was lecturer in medicine at the Royal Infirmary School of Medicine—one of the band of distinguished teachers (Mitchell Banks, Richard Caton, Alexander Davidson, William Carter, Rushton Parker) that gained for the school a high reputation. They played a large part in the foundation of University College in 1881, Glynn becoming the first professor of medicine (1884-1922). His published work deals with many subjects, perhaps the most notable being the Lumleian Lecture on infective endocarditis, and those on hysteria and allied nervous affections.

As pupil, resident, and colleague, the writer has had ample occasion to realize the wide and sound knowledge Professor Glynn had, founded on careful bedside work coupled with thorough study of morbid anatomy, the value of the correlation of clinical signs and pathological features never being overlooked. He was a brilliant teacher, but to his students something more—a genial comrade, always appreciative of a good story and ready to cap it. In his earlier years Glynn was a great swimmer, and later, when longer holidays became possible, he practised his artistic gifts (at one time he worked with the late Robert Fowler, R.I.) and reached almost a professional standard. Many of his paintings were exhibited at the Royal Liver Society, and some at the Liverpool Autumn Exhibitions. The University possesses a valuable series of drawings of morbid conditions, notably those of heart lesions. He had, too, a good knowledge of music, and was a vocalist of considerable ability.

Professor Glynn, a widower, leaves three daughters and four sons, and to them we offer our sympathy in their loss, and it goes especially to the two daughters who have so helped to make the last years of their father's life such happy ones.

J. H. A.

Dr. CHARLES MACALISTER writes:

A memoir of the late Professor Thomas R. Glynn is, I understand, being written by one who was associated with him academically for many years, and the history of his career, and of his association with the Liverpool School of Medicine throughout the various phases which led to its becoming a very important faculty in the University of Liverpool, need not be reiterated. It is of the man himself and of the influences of his work and of his personality that I venture to add a few words of appreciation.

It was not as a student of the school that I had the advantages of his teaching. As a young practitioner one soon realized that he was a master of clinical medicine, the dynamic power of whose teaching attracted those fortunate enough to be able to attend his clinic. Every man's life involves a history, and, so far as our profession is concerned, it was the fact that Dr. Glynn was a great clinical observer and teacher which rendered his life so essentially valuable. He belonged to the days when specialism had not as yet split up the work of the physician. He taught general medicine, of which his knowledge was wide, on broad lines eminently educative, not only in the way of impressing clinical facts, but, importantly, in that of cultivating the principles of observing the meanings and associations of these facts. The value of his influence as a teacher is reflected by the circumstance that very many members of the hospital staffs were his pupils, who carry on the traditions of his work. To his immediate students, who were attracted in large numbers to his wards, he was a kind of god, an oracle whose word was beyond dispute. I recollect many years ago discussing a case with a young resident who had been one of his pupils. He held very definite opinions about the case in question, and, on inviting his reasons, his answer was, "Because Dr. Glynn thinks differently from most people about these cases," or words to the same effect, which indicated that he meant to hold by the teaching of his master whatever others might think of the matter. Dr. Glynn's quickness of perception was illustrated by his noting an ill-looking boy in the out-patient room becoming distressed by a draught from an opening door. He at once suspected that the lad might be suffering from rabies, which proved to be the case. When calling on Dr. Glynn last year I reminded him of

the incident, which must have happened more than forty years ago, and he was much interested to hear that I remembered it. His teaching was largely based on his knowledge of pathology, and at the Medical Institution and in his class-rooms his expositions were frequently illustrated by excellent water-colour paintings of specimens of fresh preparations, and also of clinical conditions.

Dr. Glynn's life was a busy one. A large consulting practice, added to his professorial and hospital work, afforded him little time for leisure. In the 'nineties it used to be said that it was hardly proper for any well-known citizen to die without being seen by him or by another eminent contemporary physician. His temperament, however, was one of great activity, and it would have been impossible for him to leave any time unoccupied. He was an artist of considerable merit, and had a fine appreciation of colour. As a landscape artist he produced many paintings which, in some respects, resembled those of Robert Fowler, who was frequently his guest during the summer vacations. I expect that Fowler interested him beyond the artistic side of his character in that he suffered from agoraphobia, and invariably had a companion with him when he was working. Another aspect of Dr. Glynn's life was his love of music. He was an organist, and he delighted in singing. He retained his singing voice even when he was over 80 years of age. He had a great sense of humour, which permeated both the professional and social sides of his life. He, Sir Mitchell Banks, and Edgar Browne were a never-failing source of entertainment at dinners and social functions. At the Chester Medical Society's annual dinners, for example, the spontaneous wit and repartee emanating from all three of them were as much an annual event as the dinners themselves.

On the death of an old friend memories of the past crowd in to the mind; but one must forbear reference to them, and while rejoicing that a long life given to useful work and to the establishment of indelible traditions has been lived, yet we mourn in that we shall neither see nor hear again one who has been a devoted friend to, and a distinguished member of, our profession.

[The portrait reproduced is from the painting by R. E. Morrison.]

Universities and Colleges

UNIVERSITY OF LONDON

A special meeting of the University Court, on May 18th, had before it a letter from the clerk to the Goldsmiths' Company, stating that the Court of the Company had had under consideration the prospective needs of the University in connexion with the establishment of its own headquarters in Bloomsbury, and has decided to offer, subject to the consent of the Charity Commissioners, and to certain other conditions, a sum not exceeding £50,000 towards the cost of erecting and equipping the library building of the new headquarters. The Court, in accepting this munificent offer, has conveyed to the Goldsmiths' Company an expression of its cordial thanks and high appreciation of this further evidence of the interest taken by the Company in the life and growth of the University.

UNIVERSITY ENTRANCE SCHOLARSHIPS

Combined Hospital Examination

The Medical Schools of Guy's and St. Thomas's Hospitals, and the Medical College of St. Bartholomew's Hospital, have recently had under consideration the methods of award of university entrance scholarships, and are unanimously of opinion that, in the interests of medicine, scientific merit and attainments should be the determining factors. They have therefore agreed that their university entrance scholarships shall be awarded as a result of open competitive examination, and they have arranged to hold a common examination for the purpose. Each school offers annually a scholarship of £100 and an exhibition of £60, and the scholarships and exhibitions will be awarded by the deans of the three schools sitting in conference, after receiving reports from the examiners. The scheme will come into operation in July, 1932, when the examination will be held at St. Thomas's. Thereafter the examination will be held at each of the schools in rotation. Candidates will, of course, be entitled to express their preference for any particular school, and the stated preference will be taken into consideration when the scholarships are awarded. They will be open to students who have completed their examinations in anatomy and physiology in a British school or university outside the London metropolitan area.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on May 14th, when the President, Lord Moynihan, was in the chair.

Mr. Ernest F. Neve and Mr. G. H. Edington were introduced and admitted Fellows of the College.

Diplomas

Diplomas of Membership were granted to 161 candidates. (The names were published in reports of meetings of the Royal College of Physicians of London printed in our issues of May 9th, p. 820, and May 16th, p. 873.)

The diploma of Fellowship was granted to Alfred Richard Denis Pattison.

The Diploma in Gynaecology and Obstetrics was granted, jointly with the Royal College of Physicians, to Wallace Freeborn.

Honorary Gold Medal

The Honorary Gold Medal of the College was awarded to Mr. G. Buckston Browne, in recognition of his valuable contributions to the surgery of the genito-urinary system, and of his great liberality in the endowment of an Institute for Surgical Research.

Fellowship Examinations

The Huddersfield Royal Infirmary was recognized for the twelve months' surgical practice required of non-Members before admission to the Final [illegible]

The secretary reported that [illegible] had applied for admission to the [illegible] for the Fellowship to be held in Australia.

Vacancy on Court of Examiners

The President reported that the vacancy on the Court of Examiners occasioned by the retirement of Mr. L. Bathe Rawling would be filled up at the ordinary meeting of the Council on June 11th.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Lectures

At a meeting of the Royal College of Physicians held on May 14th, with the President, Lord Dawson of Penn, in the chair, the following lectureships were announced:

Lumleian (1932), Dr. C. E. Lakin.
Goulstonian (1932), Dr. L. J. Witts.
FitzPatrick (1932), Dr. James Collier.
Croonian (1933), Dr. W. E. Dixon.

Diploma

A Diploma in Gynaecology and Obstetrics was granted, jointly with the Royal College of Surgeons, to Wallace Freeborn, M.B., Ch.M.Sydney.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

A meeting of the Royal College of Surgeons of Edinburgh was held on May 13th, when Dr. James Haig Ferguson, President, was in the chair. The following twenty-three successful candidates out of eighty-three entered, who passed the requisite examinations, were admitted Fellows:

W. A. D'A Adamson, S. S. Ahluwalia, G. L. Alexander, A. L. Dawkins, H. E. Emmett, E. L. Farquharson, G. J. Hanly, R. W. Hendry, R. W. Johnson, I. Kallmeyer, C. H. Leedman, J. F. Macdonald, L. G. McQueen, B. T. Mayes, S. J. G. Naim, Belinda E. Nesbitt, P. Pattabhiramaiya, A. A. Pullar, I. M. Robertson, K. G. W. Saunders, W. G. E. Shand, G. D. Shaw, W. C. Wickremesinghe.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, was, after a competitive examination in materia medica, awarded to N. W. Nisbet (Edinburgh).

Medical News

The Royal College of Physicians of London will be closed to-day (Saturday, May 23rd) and on Monday, May 25th.

The house and library of the Royal Society of Medicine will be closed to-day (Saturday, May 23rd) and on Monday, May 25th.

The annual summer dinner of the Glasgow University Club, London, is to be at the Café Royal, 68, Regent Street, W., on Friday, June 12th, at 7.30 p.m., with Professor Gilbert Murray, LL.D. in the chair. Any Glasgow University men who, though not members of the club, would like to be present are invited to communicate with the honorary secretaries, 62, Harley House, N.W.1.

A garden party in aid of the educational work of the Royal Medical Benevolent Fund Guild will be held at the Royal Botanic Gardens, Regent's Park, N.W., on Tuesday, June 2nd, from 2.30 to 8.30. H.R.H. the Duchess of York (patroness of the Guild) has consented to be present. Particulars and tickets of admission may be had from the honorary treasurer, Mrs. E. D. D. Davis, 46, Harley Street, W.1. (Telephone, Langham 1178.)

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, May 28th, at 8.30 p.m. Dr. Nathan Raw will read a paper on dangerous drugs; a discussion will follow.

The fourth Hugh Owen Thomas Memorial Lecture will be given in the Liverpool Medical Institution on Thursday, May 28th, at 4.30 p.m., by Mr. D. McCrae Aitken, F.R.C.S. The subject will be "Principles of rest and exercise in the treatment of joints."

The annual oration to the St. John's Hospital Dermatological Society will be given on Wednesday, May 27th, at 5.30 p.m. by Dr. S. Lomholt of Copenhagen, on the effects of concentrated ultra-violet light upon the skin, and its uses in dermatological therapy.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found at page 208 of the *Supplement*. The special evening lectures to candidates for the M.R.C.P. are being continued. Copies of syllabuses for all courses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

At the meeting of the Central Midwives Board for England and Wales on May 7th the correspondence included letters from the Ministry of Health enclosing, for the information of the Board, copies of the Colchester, Lowestoft, and Walthamstow (Supervision of Midwives) Orders, 1931, which Orders create the borough councils of those places respectively local supervising authorities. It was agreed, on the motion of Dr. J. J. Buchan, "That the chairman of the Board, for the time being, be, by virtue of his office, a member of all committees of the Board, and of all subcommittees which may, from time to time, be appointed by such committees or any one of them."

The New York correspondent of the *Times* records the exhibition, on May 16th, at the General Electric Laboratories at Schenectady, of an *x*-ray tube having a power far beyond that of any other yet devised. Within the tube electrons were discharged at a speed of 184,000 miles a second, under the pressure of an electrical current of 900,000 volts. The rays, after penetrating a layer of copper three millimetres thick, and then 4 inches of iron, were still powerful enough to take an *x*-ray picture. The tube has been made by Dr. W. D. Coolidge, and it will be used in the Memorial Hospital, New York, for the treatment of cancer.

The committee of award has made appointments to twenty-seven Commonwealth Fund Fellowships tenable by British graduates in American universities for the two years beginning September, 1931. These fellowships are offered by the Commonwealth Fund of New York, of which Mr. Edward S. Harkness is president. The list includes the name of J. H. Biggart, M.B., B.Ch., B.A.O., Queen's University, Belfast, who is appointed to Johns Hopkins University, Baltimore, with a fellowship in medicine.

The fifty-fifth Congress of the German Society for Surgery was held at the Langenbeck-Virchow House, Berlin, on April 8th, under the presidency of Professor Schmieden of Frankfort-on-Main, when the chief subject discussed was the surgery of the peripheral nerves, introduced by Professor Kuttner of Breslau.

The third International Congress of Radiology will be held in Paris from July 26th to 31st, when the following subjects will be discussed: radiological examination of the mucosa of the alimentary canal; radiological examination of the urinary system by excretion of opaque substances; pre- and post-operative treatment of mammary cancer (recurrences and metastases excepted); radiotherapy of inflammatory diseases; and diathermy in inflammatory diseases. The subscription is 300 francs for members of the congress, and 50 francs for persons of the members' families. Members of the congress will be allowed a reduction of 50 per cent. on their fares when travelling on French railways to and from the congress. Summaries of communications, not exceeding 400 typewritten words in English, French, or German, should be sent to the office of the congress, 122, Rue la Boëtie, Paris, VIIIe.

Dr. C. P. Oliver, C.B., C.M.G. of Maidstone has been appointed a deputy lieutenant for the county of Kent.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal) exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Inflammation at Site of Old Vaccination Scars

Dr. WILLIAM J. LEDGERWOOD (Holsworthy) writes: Could any of your readers give me an explanation of the following case, and suggest what treatment might be employed? A girl, aged 16, came to me last September complaining of great pain and stiffness in the left upper arm. The arm in the region of the vaccination scars was red, hot, swollen, and very tender. Three of the vaccination scars (the vaccination having been performed in infancy) were of a dark purple colour. She told me that the trouble began in the scars, which became purple and painful, and then the surrounding skin became inflamed. Later, small vesicles formed on the inflamed skin, and eventually, after about six weeks, during which many applications were tried, the condition cleared up, the vaccination scars looking quite normal. She has just returned to me, complaining of pain in the arm and with purple discoloration of the same three vaccination scars.

Income Tax

Allowable Expenses

"G. C. M." asks for a statement of the expenses which a general practitioner can claim, and of the proportion allowable in each case, and also as to the basis of liability in a *new practice*.

*** It is perhaps simplest to consider expenses as falling under one of three heads—entirely professional, almost entirely professional, and general. The first is, of course, simple, and includes drugs, medical stores, upkeep of instruments, medical subscriptions, and so on. It should, however, be remembered that it is the ordinary annual expenditure which is allowable; the cost of setting up a dispensary or acquiring or adding to a set of instruments is capital outlay, and not deductible. Where almost the whole cost is incurred for professional purposes, the usual method of dealing with such expenses is to charge the whole amount *less* a sum which represents the personal advantage—this covers such expenses as car (running costs and depreciation), telephone, and chauffeur's wages and board. No general guide can be given as to the amount to be treated as "personal"—circumstances differ so widely. With regard to the general house expenses—rent and rates, gas, coal, etc.—probably the most common ratio in provincial practices is one-half, but here again a good deal depends on circumstances—for example, if a specially high rent is being paid for a specially desirable site for professional reasons, one-half may not be adequate, and, on the other hand, if it does not include a garage, it may be excessive. As regards domestic servants, it is apparently fairly common to allow the cost of one where two or more are kept, the cost, of course, to include food, laundry, etc. On the "general" expenses question it is sometimes helpful to look at the reverse position—that is, to inspect the balance of such expenses after the professional proportion has been deducted, and see whether that is reasonable, having regard to what the practitioner and his family get first and to local conditions generally. With regard to the basis, the position is as follows: for the first year, the earnings of that year; for the second year, the earnings of the first year, unless the second year's earnings are less, in which case the taxpayer can claim a revision of the assessment to the profits of the second year; for the third and subsequent year, the earnings of the previous year. The cash basis will not be accepted for the calculation of the earnings of the first two years of a new practice.

Private use of Car

"R. B." has for some years treated one-tenth of the cost of running his car as representing private use. He has expended £150 in replacing his car, and the inspector claims that one-tenth of that sum should similarly be ignored in computing his professional expenses.

*** There seems to be no valid legal difference between running costs and replacement expenses in this connexion. If in fact the car has been used one-tenth for private and nine-tenths for professional purposes, then one-tenth of the £150 represents costs incurred through private use, and is not deductible for income tax purposes.

LETTERS, NOTES, ETC.

Ulcerative Colitis

DR. T. GERALD CARRY (Montecatini, Italy) writes: Dr. Hurst, in his very interesting paper in the *Journal* of April 25th, suggests that bacillary dysentery and ulcerative colitis are identical, in other words, that the colitis is a sequela of the dysenteric condition. I venture to say that few with experience of these affections in tropical or semi-tropical countries will agree with this view. In Egypt, where bacillary dysentery is prevalent, ulcerative colitis is comparatively rare, and I can recall but one instance among hundreds where the condition became chronic and ended in ulcerative colitis. On the other hand, among Americans colitis is extremely common—indeed, at one time it threatened to become a fashionable malady—until attention was focused on the unfortunate gall-bladder. Among Americans colitis is certainly not due to the *B. dysenteriae*, but rather to the inordinate use of "canned" food to the exclusion of fresh food—fruit and vegetables especially. Bacillary dysentery is very amenable to energetic treatment; Glauber's salts, etc., will be found more effective than serums or vaccines, while in chronic colitis, which is prevalent at spas, it is found that a cure is frequently effected without the use of crude mechanical devices for diagnosis or treatment. The bile is the natural intestinal disinfectant, hence the efficacy of certain natural mineral waters with a specific action on the liver.

Pregnancy with Intact Hymen

DR. G. M. HODGES (Deddington, Oxon.) writes: Dr. Sefton's letter in the *Journal* of May 2nd (p. 780) interested me, as I saw a similar case some years ago. An unmarried woman, aged 23, consulted me in March on account of four months' amenorrhoea and was found to be pregnant. She denied coitus, and was at her own request examined. The hymen was found to be quite intact, with a central opening that admitted nothing larger than a lead pencil. The hymen was not unduly elastic or sensitive. On questioning, it appeared that her "young man" had emitted semen on or between the vulvae on several occasions without any attempt at penetration. Coitus after marriage was quite painless, and when seen before delivery in the August the hymen presented the usual latero-posterior tear.

DR. MARIE C. STOPES writes: In his note under the above title (May 2nd, p. 780) Dr. J. Sefton draws deductions from his statement "the sperm is said to die within a few hours of deposition in the vagina (unless it enters the cervix)." Such deductions are not necessarily correct, for sperms have been found alive in the vagina as long as seventeen days after their deposition; much will depend on the degree of normal acidity in the vaginal secretions of the individual woman, a point of great personal variability. Facts and discussions on these very interesting points are to be found in my book *Contraception, Its Theory, History, and Practice*, Chapter VI.

Clinical Thermometers

MESSRS. G. H. ZEAL, LTD. (London), write: Our attention has been called to Dr. Robertson's letter (*Journal*, May 9th, p. 830) and the statements made therein, and we are writing to point out that the method of testing the fourteen clinical thermometers adopted by Dr. Robertson could not possibly give satisfactory results. It is a well-known fact that water in a vessel varies considerably in temperature in various parts of the vessel unless the following conditions exist: (1) a suitably constructed vessel; (2) effective heating—preferably electrical; (3) an efficient stirring apparatus. Without these three factors the temperature of the water varies appreciably in different parts of the vessel. It is also necessary to keep the mercury bulbs of the thermometers well apart in order to allow an effective flow of water between each instrument, and unless special apparatus is available, such as is used by the National Physical Laboratory and by the leading manufacturers, no degree of accuracy or uniformity of reading can be guaranteed.

Visit of Scientists to Russia

We are asked to say that arrangements have been made for a second party of scientists to visit Soviet Russia this summer. It will leave London Bridge for Leningrad on August 8th, returning to London in time for the British Association Meeting. The return fare is £18 inclusive, and the latest date for receiving applications is June 15th. Applications and inquiries should be addressed to the secretary, Society for Cultural Relations, 1, Montague Street, London, W.C.1.

Medical Golf

The annual golf competition for members of the West Suffolk Division of the British Medical Association was held at Worlington on May 14th. The following took part: Drs. F. R. Barwell, B. E. A. Batt, J. D. Batt, W. F. Bennett, J. W. E. Cory, E. C. T. Clouston, O. G. Clouston, G. Garratt, E. C. Hardwicke, D. J. P. O'Meara, C. Tylor, A. L. Ritchie, and Colonel A. D. Waring. Dr. J. D. Batt and Dr. A. L. Ritchie tied for first, one down to bogey. They will play another match.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, 48, 49, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 207.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

489 Hepatic Insufficiency

M. LABBÉ (*Ann. de Méd.*, February, 1931, p. 97) points out that, clinically, functional disorders of the liver play a very important part, greater perhaps than do anatomical lesions, and that a systematic examination and study of its functions will reveal hepatic insufficiency in many morbid conditions in which it is unsuspected. The biliary, glycogenic, proteolytic, and haemopoietic functions of the liver, and their pathological variations, are described. Many urine and blood tests are enumerated, and their significance in revealing hepatic insufficiency is demonstrated. One test alone is not an index of functional disorder, and many must be performed in order to reach a diagnosis; the liver, pancreas, and endocrine glands co-operate in the glyco-regulating function of the body, hence glycosuria of itself does not indicate hepatic trouble, as it does when associated with urobilinuria and cholaluria. Moreover, tests of the primordial hepatic functions (biligenesis, the metabolism of the carbohydrates, albumins or fats, and coagulation of the blood) are the most important. In conclusion, Labbé cites and briefly discusses the various conditions in which there is an underlying, unsuspected hepatic pathogenesis which can be demonstrated only by a complete examination such as is described.

490 Prognosis in Spasmophilia

U. HJÄRNE (*Acta Paediatrica*, March 15th, 1931, p. 281) states that the view has been maintained in the German paediatric literature of the last twenty-five years that the majority of children who have shown signs of spasmophilia, such as convulsions, laryngospasm, or tetany, subsequently present an abnormal psychical development and tend to suffer from neuropathy, psychopathy, and imbecility. A close examination, however, of the investigation on which this view was based revealed that only a small proportion of the formerly spasmophilic children had been subsequently examined. Hjärne in 1930 examined 29 children who had been treated for spasmophilia at the Upsala University children's clinic from 1916 to 1924, and found that their physical and mental development was completely normal apart from the teeth, which were almost always characterized by considerable caries, while half the cases presented hypoplasia of the permanent incisors.

491 Calcareous Aortic Valvular Disease

H. M. MARGOLIS, F. O. ZIELLESSEN, and A. R. BARNES (*Amer. Heart Journ.*, February, 1931, p. 349) have made an etiological, pathological, and clinical study of calcareous aortic disease occurring without significant degrees of involvement of other valves. They have investigated 42 consecutive cases coming to necropsy during the past eight years. In only three of these patients had there been a history of rheumatism, while only four showed definite or suggestive evidence of syphilitic infection. Males were affected four times more often than females, and 35 of the patients were more than 50 years old on first presenting themselves for examination. Only six patients complained primarily of symptoms referable to the heart. Clinical evidences of peripheral arterio-sclerosis and of cardiac enlargement were found in about half the cases. Hypertension was noted in twelve patients. The signs on auscultation were very variable. Abnormalities in the electrocardiogram were comparatively uncommon; inversion of the T-wave in a significant lead was observed in five, and left ventricular preponderance in nine patients. Roentgenograms usually confirmed the clinical evidence of cardiac enlargement. Except for occasional slight atheroma of the mitral cusps, pathological changes were found in the aortic valve alone. These consisted chiefly in calcareous deposits in the valve leaflets producing distortion and stiffening with varying degrees of stenosis or insufficiency, or both. In several instances intimal proliferation of the arterioles of the aortic ring was observed, and hyalinization extended into the aortic tissues from these vessels. It is thought that these obliterative changes in the aortic ring result in ischaemia of the valve cusps, and that degenerative changes, with subsequent calcification, ensue. In a few cases, both clinical and pathological data pointed to a rheumatic origin, or to an inflammatory process involving the nutrient arteries of the aortic valves.

492 E. L. TUOHY and P. F. ECKMAN (*Minnesota Med.*, April, 1931, p. 289) report cases of gross enlargement of the heart associated with local lesions in the aortic cusps which induced marked aortic stenosis. They consider that it is insufficiently realized that the appearance of calcareous nodules in these valves can produce very large hearts with thick dilated left ventricles, even though no outward signs or symptoms of the process are observable. This local process may develop much earlier than the usual atheromatous series of changes, and is often seen most typically in patients outside the age limit of rheumatic cardiac complications. With the syndrome there are associated no inflammatory reactions, but it can so modify the base of the aorta as to give rise to typical angina without the characteristic narrowing along the course of the coronary arteries. Such nodular lesions are said to be curiously unlike the ordinary intimal atheroma commonly seen within the endocardium and intima of the aorta, the calcification process being one of media degeneration and infiltration. If death does not supervene from other causes, this lesion can lead to an extreme degree of aortic stenosis with great enlargement of the heart. The authors urge the importance of more careful attention to the determination of the heart outline in all suspicious cases, and suggest that it is unwise to exclude the possibility of aortic stenosis even in the absence of multiple involvement of the valves and of a rheumatic or syphilitic history.

Surgery

493 Renal Carbuncle

B. LIPSHUTZ (*Annals of Surgery*, March, 1931, p. 766) describes carbuncle of the kidney as a rare but definite lesion, which is probably more common than is generally believed. The primary focus is usually some staphylococcal infection of the skin, such as carbuncle or hard furuncle, or the condition may follow mastitis, osteomyelitis of the finger, angina, or even influenza. The average interval between the healing of the primary infection and the appearance of a renal or pararenal infection is from three to five weeks. In some cases trauma has been noted as a definite cause. The infection begins in the interstitial portion of the cortex of the kidney, and is usually of haematogenous origin. The first change produced in the kidney is an infarct, which is always directed towards the cortex of the kidney, with the apex towards the pelvis. This pyramidal-shaped infarct is soon converted into a suppurative focus. The symptoms are those of a mild or severe septicaemia, with a fluctuating temperature, and pain which varies in intensity from a dull ache to a sharp localized pain. Tenderness is most acute in the region between the twelfth rib and the muscles of the loin, and there may be some restriction of the respiratory movements of the affected side. The most common urinary finding is a trace of albumin, a few red cells, and some leucocytes. A correct diagnosis is seldom made before operation. When the other kidney

is normal, nephrectomy is the operation of choice, and may be performed successfully even though there is toxic nephritis in the other kidney. If the infection is limited to a small area of the cortex, resection of the infected kidney focus may be feasible. The infarct in the early stage of the infection can easily be removed, and the cavity be packed with gauze, the wound being left open to prevent an extensive area of infection. The prognosis is good when the diagnosis is made early, and the operation is carried out while the infection is in its initial stage, consisting only of a circumscribed zone of multiple suppurative foci.

494 Surgical Treatment of Raynaud's Disease

T. MARIO (*Rif. Med.*, February 9th, 1931, p. 203) reports a case of Raynaud's disease treated by sympatheticectomy of the periarterial branches, and later by arterio-venous anastomosis; the condition began with an attack of rheumatic polyarthritis fourteen years previously. In spite of various medical applications signs of gangrene appeared in the toe, and periarterial sympathectomy was performed. This was followed by considerable improvement for a short time, but eventually the disease spread and amputation became necessary. Three years later similar symptoms began to appear in the other foot, and as no improvement followed the usual treatment, the author tried the effect of arterio-venous anastomosis, with the idea of improving the circulation. This operation gave rise to considerable relief, but after about a month the condition became as bad as before. The author discusses the various theories as to the causation of Raynaud's disease and the different suggestions as to treatment. The temporary improvement following arterio-venous anastomosis is, he thinks, probably due to passive hyperaemia. The effect of cold or hot applications may help in differentiating gangrene due to Raynaud's disease from that caused by arterio-sclerosis; in the first, warmth does good, while in arterio-sclerosis cold applications are of more use. In spite of occasional cures, none of the various medical or surgical treatments can be relied on as certain or specific.

495 Parathyroid Tumour and Generalized Fibro-cystic Osteitis

I. SNAPPER (*Bruxelles-Médical*, March 15th, 1931, p. 585) reports a case in which a parathyroid tumour was found to be responsible for symptoms of "osteomalacia." Five years previously the patient, a man aged 56 years, had complained of a slight stiffness of the legs which increased to actual pain. The patient had lost weight, and for a year he had been bed-ridden and cachectic. A month before being seen by Snapper he had had a spontaneous fracture of the right femur. Radiographs showed an extreme decalcification of the pelvis and femora, which explained the previous diagnosis of osteomalacia. The patient appeared to be in a desperate state; the blood calcium was 20–23 mg. per cent. A radiograph which had been taken in Antwerp in 1925 showed the characteristic changes of a cystic fibrositis of the second metatarsal and of the left glenoid cavity. It appeared probable that the patient was suffering from Recklinghausen's disease; the high blood calcium figure pointed also to the presence of a tumour of the parathyroid. An adenoma 2.5 cm. by 1.5 cm. was in fact removed from the left parathyroid. The result was good; sixteen months after the operation the patient could walk with a stick for one hour, had no pain, and felt himself cured. Radiographs showed a marked recalcification of the pelvis and femora. Immediately after the operation, owing to the rapid fall in the blood calcium, injections of parathyroid extract and intravenous injections of calcium were necessary. Later, oral administration of calcium lactate sufficed to maintain the equilibrium of calcium metabolism. The markedly good results of the operation proved that the removal of a parathyroid adenoma exercised a salutary influence on the Recklinghausen's disease even when the late stage of pseudo-malacia was present. Snapper suggests that there may be some connexion between parathyroid tumour and true osteomalacia.

Therapeutics

496 Malaria Therapy in Neurosyphilis

In a survey of the medical aspects of malaria therapy in neurosyphilis G. S. JOHNSON and R. A. JEFFERSON (*Journ. Nerv. and Ment. Dis.*, April, 1931, p. 405) enumerate the contraindications as: the existence of rapidly progressive paresis and far advanced tabes, with incontinence and severe ataxia; juvenile general paralysis; primary optic atrophy; severe cachexia, or the presence of such systemic diseases as diabetes, nephritis, and active pulmonary tuberculosis; and a history of attacks of heart failure in a case presenting clinical evidence of morbus cordis. The authors agree that high fever is not the primary therapeutic agent, and believe that improvement is due to a tissue reaction which builds up immunity in the nervous system. Excessive high fever is neither necessary nor desirable, and every effort should be made to keep the temperature consistently below 106° F. A course of eight paroxysms is considered sufficient; longer periods of treatment debilitate the patient and damage his recuperative powers. The authors have found that 35 per cent. of such cases show evidence of aortic or cardiac disease, and believe that the incidence of this complication is even higher. Circulatory collapse may occur during malaria therapy; it is apparently brought about by severe fatigue due to disturbance of the vasomotor tone. Treatment is similar to that for shock, and the malaria therapy must be promptly terminated; digitalis is ineffectual in such cases. The authors believe that a systolic blood pressure below 90 mm. of mercury is not a dangerous sign during treatment; in many of their patients it remained consistently around 70 without any adverse sequels. They urge that the criterion for malaria therapy should be the physical condition of the patient rather than his mental state. Careful attention to the medical aspects will lower the mortality rate, and carry even the less hopeful cases through treatment satisfactorily: Antisyphilitic chemotherapy is valuable before malaria is induced, especially in debilitated cases, and it is highly advisable after the malaria has been terminated.

497 Precautions during Arsphenamine Administration

In 1919 Davis and Whipple reported that diets rich in carbohydrates afford protection against liver injury caused by chloroform, whereas diets rich in fat and protein predispose to hepatic disturbance; it was subsequently assumed that the same conclusions might be applicable to the toxic effects of arsphenamine. E. B. CRAVEN, jun., (*Bull. Johns Hopkins Hosp.*, March, 1931, p. 131) doubted whether such a conclusion was justifiable in the case of two drugs chemically so dissimilar, even though the type of liver injury, central necrosis, was the same in both. Experiments were therefore devised to test the three principal diets—namely, high in carbohydrate, high in fat, and high in protein—against the liver injury produced by arsephenamine. Craven found that diets rich in fat and protein gave the maximum protection against such liver injury, the fat being definitely more efficacious in this respect. Diets containing large quantities of carbohydrates seemed to confer on the liver the maximum susceptibility to hepatic intoxication during the administration of arsphenamine; another predisposing factor of the same kind was starvation. This action of carbohydrate dietaries was not modified by the addition of cystin to them, or its intravenous injection. Craven, therefore, disagrees with the established practice in certain clinics of placing patients suffering from arsphenamine jaundice on a high carbohydrate diet.

498 Barium Chloride in Typhoid Fever

E. PETRINA (*Il Policlinico*, Sez. Prat., March 30th, 1931, p. 437) publishes brief notes of six cases of typhoid fever treated with barium chloride, and refers to 23 other cases in which this salt was tried. In spite of the reputation of extreme toxicity attached to this drug, the author encountered no bad results from its administration, except

in one instance where it caused vomiting. He gave 1.5 grams each day, in three divided doses, for five days; allowed a five-day interval, and then repeated the administration for a second period of five days. The benefit appeared in the form of clearing up the stuporose condition, cleansing the mouth, lessening the meteorism and enlargement of the spleen, and hastening the disappearance of the rash. The presence of considerable albuminuria proved no drawback in this treatment, and all the patients recovered.

499 The Glucosides of Squill in Acute Scarlatinal Nephritis

A. STROE and P. KLINGER (*Paris Méd.*, April 11th, 1931, p. 357) report a series of 21 cases of scarlatinal nephritis, of which 9 were of the hydraemic, 5 of the azotaemic, and 7 of the mixed types, which were treated by squill glucosides. Scillarene was used in the form of tablets containing 0.000S gram, or as a solution of 0.00S gram. in 1 c.cm., two to three tablets or 20 to 30 drops being given daily. The daily administration was continued until improvement was shown by reduction of the oedema, fall in the blood urea, or increase in the output of urinary urea. The minimum time for the appearance of any improvement was forty-eight hours, and treatment has been continued for as long as thirty days without the development of toxic signs due to accumulation of the drug. Some patients were admitted with marked oedema; in these it was difficult to assign the amount of improvement due to the specific diuretic, and to the usual dietetic and hygienic measures, but in the case of those admitted early to hospital the authors have no doubt that the drug materially hastened recovery. Only one instance of intolerance to the drug was noted, vomiting supervening and preventing further trial; in one case there was no improvement, and in a third the drug failed, as did every other possible therapeutic measure. In no case did the appearance or increase of epithelial casts or red blood cells in the urine give evidence of renal damage by the drug. The authors consider that the failure of this powerful diuretic to damage the essential renal tissues supports the hypothesis of Chabanier and Blum assigning an important role to the extra-renal tissues in the mechanism of chloride retention.

Laryngology and Otology

500 Pathogenesis of Aural Cholesteatoma

D. MCKENZIE (*Journ. of Laryngol. and Otol.*, March, 1931, p 163) reviews the etiology of causation of cholesteatoma, but declines to endorse the theory of epidermal invasion, or that of metaplasia. Primary cholesteatoma, a rare but definite condition, is described in detail, and a full account is given of the microscopical structure and the behaviour of primary and secondary cholesteatoma. Three theories are advanced to explain the expansion of the cholesteatomatous cavity: (1) simple pressure atrophy; (2) some chemical action; and (3) invasion of the Haversian systems, a theory first advanced by Kirchner. McKenzie, however, favours the pressure atrophy theory. Attention is drawn to cholesteatomata, which occur rarely in the basal cisternae, and which are now believed to be inclusion tumours, they closely resemble aural cholesteatomata in their microscopical appearance. The conclusion drawn is that all cholesteatomata are primary, and that the so-called secondary cholesteatoma is one which has broken through its limiting membrane and become secondarily infected. The theory that cholesteatoma is an inclusion tumour brings aural and cerebro-spinal cholesteatomata into line, and the site of origin in the aditus-antrum region, where many elements meet, favours this theory. McKenzie, however, is not convinced of its validity. This account has one important bearing on treatment—namely, the removal of the thin plate of bone in the aditus-antrum region, if the disease is limited to that small area. If symptoms of wider infection are absent the mastoid operation is avoided, and many hearing ears may be saved.

501 Treatment of Peritonsillar Abscess

G. CANUYT (*Ann. d'Oto-Laryngol.*, January, 1931, p. 61) describes investigations which he has made in order to discover the exact site of pus collection in the so-called antero-superior peritonsillar abscess. The tonsillar region in a fatal case was dissected carefully, and fluid was injected into the peritonsillar region in dissecting-room subjects. These experiments led the author to the belief that the abscess is situated between the tonsillar capsule and the pharyngeal wall. *X*-ray examination of the living after the injection of lipiodol, and the conditions met with in a series of tonsillectomies during the acute stage of peritonsillar abscess, pointed to the same conclusions. In describing his technique of treatment the author recommends exploratory puncture with a wide-bore needle, and aspiration in every case. This, and the further incision of the abscess, is conducted under infiltration anaesthesia, which has always proved effective. If pus is found on exploration, the abscess is then opened by a long incision through the anterior pillar of the fauces, and by the opening up with blunt instruments of the tonsillar fossa between the capsule and the pharyngeal wall. This approach provides free drainage from the most dependent part of the abscess, and is in accordance with general surgical principles. Canuyt recommends that the first incision should be made with an electro-surgical instrument if this is available. In conclusion, it is emphasized that the best prophylaxis of peritonsillar abscess is complete tonsillectomy.

502 Acute Inflammation of the Auditory Meatus

B. FOSTER (*Med. Journ. of Australia*, January 3rd, 1931, p. 15) reports a case which might easily have been mistaken for a furuncular abscess in the external auditory meatus had not the patient insisted that there was a foreign body in the left ear. Twenty days previously he felt something enter the ear; he could not remove it, and since the ear became increasingly sore he sought medical advice. Syringing gave but temporary relief, and the pain returned with such severity that the patient was deprived of sleep. When seen by Foster the meatus was occluded by inflammatory swelling, and there was well-marked facial paralysis of the left side. The meatus contained a large quantity of creamy material of faint pink tinge. When this was cleared away there appeared to be a bead of granulation tissue on the floor of the cartilaginous meatus. A minute foreign body, smooth and hard, and quite embedded in the floor of the meatus, was removed by aural forceps, proving to be a squashed tick about 4.5 mm. in length, which had burrowed for about half its length into the floor of the meatus. The creamy material was mainly excretion from the tick. There was no other injury apart from the small excavation in the floor of the meatus. The middle ear was intact, and hearing was unimpaired. The condition rapidly cleared up, and within three days all signs of facial paralysis had disappeared.

Obstetrics and Gynaecology

503 Monilial Vulvo-vaginitis

E. D. PLASS, H. C. HESSELTINE, and I. H. BORTS (*Amer. Journ. of Obstet. and Gynecol.*, March, 1931, p. 320) believe that vaginal fungus infections are more common than is generally believed. Opinions differ regarding the pathogenicity of monilia. Normal females may have a chronic symptomless infection. Some writers regard its presence as symbiotic. Trichomonas and monilia may exist together or separately, with or without symptoms. Animal experiments have not been conspicuously successful. Inoculation of a healthy pregnant woman from a case of mycotic vaginitis caused transient local irritation that subsided spontaneously. Vaginal inoculation with brewers' yeast is said to have relieved persistent leucorrhoea. In severe cases a granular vaginitis resembling that seen in severe gonorrhoea is observed. Inguinal lymphadenitis is rare. When found, typical white flakes

are pathognomonic. Infection may occur at any age, but is most frequently in sexually active adults; menstruation probably, and diabetes and pregnancy certainly, are predisposing factors. Monilia infection during pregnancy may produce oral thrush in the newborn child. The present authors have examined the secretions in five diabetic patients, and in every case monilia was present, although only one patient complained of irritation. Diagnosis may be made from hanging-drop preparations, by finding mycelial threads and budding elements. When mycelia are absent, a positive diagnosis can be made only by stained smears and cultures. Both mycelial and conidial forms stain well, and are definitely Gram-positive. Sabouraud's medium (dextrose-peptone-agar adjusted to a *p*H of 5.5) is the best for the detection of fungi in doubtful cases, or for confirmation, since the excess of acid inhibits growth of most symbiotic organisms, although some staphylococci and bacilli grow freely. Monilial vaginitis tends to undergo spontaneous cure, but occasionally becomes chronic. In pregnancy, delivery is followed usually by complete relief, and menstruation relieves temporarily. Local application of aqueous solution of gentian violet (1 per cent.) is most efficacious; alkaline douches may assist.

504 Pessaries and Vaginal Cancer

G. v. WOLFF (*Zentralbl. f. Gynäk.*, March 14th, 1931, No. 11a, p. 942), who records three illustrative cases, states that while it is well known that chronic irritation of a chemical, thermal, mechanical, or physical nature may frequently lead to cancer, as is shown in the case of chimneysweeps, aniline workers, pipe smokers, and tar cancer in mice, comparatively few cases have been recorded of vaginal cancer due to a long-retained pessary. The author has found only 19 examples in German literature extending over a large number of years. His own cases, however, all occurred within a relatively short period. The first patient was a woman, aged 58, who had had ten children and seven abortions, and had worn a ring pessary which had not been changed for six years. Septicopyaemia developed shortly after the institution of radium treatment, and at the post-mortem examination, in addition to vaginal cancer, septic thrombophlebitis and metastases in both lungs were found. The second patient was a woman, aged 71, a 3-para, who had worn a ring continuously for eleven years; she was still under treatment by radium. The third patient was a nullipara, aged 69, who had worn a ring uninterruptedly for thirty years, and was still under radium treatment. Histological examination of the first case showed the presence of cancroid, and in the other two of squamous-celled epithelioma.

505 The Barbiturates in Obstetrical Analgesia

M. L. AXELROD (*Anesthesia and Analgesia*, March–April, 1931, p. 64) has found, as the result of experiments, that the only barbiturates, soluble in oil and ether, that can be safely and efficiently used in obstetrics with supplemental (nitrous oxide-oxygen) anaesthesia are iso-propyl-allyl, *n*-butyl-ethyl, and methyl-*l*-ethyl-butyl. The action of these was practically identical in the same dosage. They eliminate the use of drugs which may seriously affect the infant, and have no effect on the latter; they also reduce the post-operative need of narcotics. Labour pains, and the pulse, respiration, blood pressure, and blood loss are not affected. No late after-effects have been noted, though restlessness may develop, and so the patient must be watched. Axelrod found that 1 gram of barbiturate in 2½ oz. ether and 1¼ oz. oil with 20 grains quinine gave the best results. Though in most cases the dosage was regulated according to the body weight, the maximum dose of the barbiturate never exceeded 1 gram. Premedication varies with the obstetrician. This rectal instillation is given in the first stage of labour, and is preceded by 1 oz. plain oil and the application of vaseline round the anus to prevent irritation should ether be expelled. The instillation should be given uniformly and slowly to permit of the mixture entering the colon between contractions. Light anaesthesia of twelve to fifteen hours is obtained. This method has been used in about 100 cases (6 are here reported) with only 2 failures.

Pathology

506 The Kahn and Wassermann Tests

C. H. K. SMITH and N. A. MICHAEL (*Journ. Royal Army Med. Corps*, March, 1931, p. 202) have compared the Wassermann and Kahn tests in 2,300 cases. The Wassermann technique was that described as No. 1 Method in the Medical Research Committee's Special Report Series (1918), while for the flocculation procedure Kahn's routine test was the one adopted. It was found that a "home-made" antigen for the Kahn test gave satisfactory readings, was very economical, though slightly less sensitive than the Parke Davis standardized antigen. The results of the 2,300 serums showed 96 per cent. agreements; an analysis is given of the discordant results. Disagreement was most marked in cases of primary syphilis before treatment (28); when the Wassermann reaction was negative and the Kahn negative-incomplete (a fine granulation in two tubes). In ten of these *T. pallidum* was found, and both reactions became positive later. In the remaining cases both reactions became positive later, the Kahn reaction tending to do so rather earlier than the Wassermann. In 23 cases of syphilis during or after treatment the Wassermann reaction was weakly positive and the Kahn was positive, appearing to persist longer during treatment than the Wassermann. Disagreements were also noted with septic serums, the impression being that a positive Wassermann reaction was more likely to be caused by sepsis than a positive Kahn. In favour of the Kahn test, in the author's opinion, is its great simplicity; the fact that it does not require any elaborate apparatus, or animals, permits its being performed in small laboratories.

507 The Blood Platelets in Pulmonary Tuberculosis

G. BAQUERO (*Arch. de med., cir. y esp.*, March 19th, 1931, p. 231) made a study of the blood platelets in 23 cases of pulmonary tuberculosis in various stages of the disease, with the following results. In cases of fibroid tuberculosis in which the process has shown a more or less prolonged state of stabilization with hardly any clinical symptoms, the number of the blood platelets remains the same or shows a tendency to be slightly subnormal. The same character of stabilization in the platelet values is seen in cases of fibro-caseous tuberculosis, without, however, any tendency to subnormal figures, but rather with a slight increase. This stabilization is interrupted by appreciable changes in cases of fibro-caseous tuberculosis in which complications develop. These changes give rise to an increase which may be considerable, and they are proportionate to the destructive character of the lesions. If the complications produce a high temperature the number of the platelets fails to reach the normal when the fever has subsided. In advanced fibro-caseous tuberculosis the platelets are considerably increased. When there is a marked exudative tendency the platelets are generally greatly increased, and they present certain variations. The platelets do not show any appreciable change connected with haemoptysis in pulmonary tuberculosis.

508 The Bacteriophage in the Diagnosis of Dysentery

Sonnenschein was the first to make use of the bacteriophages in bacteriological diagnosis, and he has described specific phages for typhoid and for the various types of dysentery bacilli. M. TOYODA (*Deut. med. Woch.*, March 13th, 1931, p. 451) now describes a bacteriophage isolated from hen's excreta which is specific for the dysentery group of bacilli but is polyvalent—that is, it reacts with all the members of the dysentery group though not with similar organisms, such as *B. coli*, *B. typhosus*, and the paratyphoid and food-poisoning bacteria. Toyoda has used this agent for the rapid diagnosis of the presence of dysentery bacilli in cultures from patients' faeces; all suspicious colonies, after being inoculated for twelve to twenty-four hours, are mixed with the bacteriophage and tested for lysis.

SUNSHINE GLAXO

Sunshine Glaxo is made from the milk of selected dairy herds that are pasture-fed throughout the year.

Sunshine Glaxo is of the highest bacterial purity. The most stringent bacteriological control is exercised at all stages of its manufacture.

Sunshine Glaxo is free from B. Tuberculosis.★

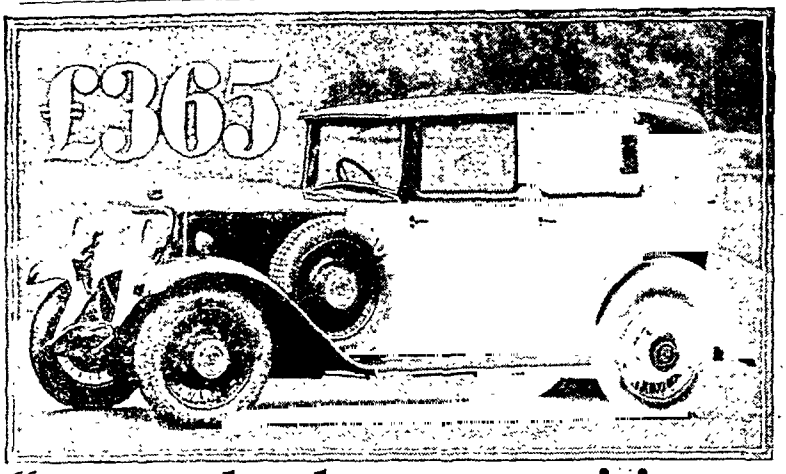
To recommend Sunshine Glaxo is to ensure freedom from milk-borne infections.

Sunshine Glaxo provides all the desiderata for the artificial feeding of infants:

(1) Milk of assured bacterial purity;
(2) Humanised formula;
(3) Optimal vitamin and mineral content.

★ As part of the routine of bacteriological control Sunshine Glaxo is regularly examined for absence of B. Tuberculosis by inoculation test. No positive reaction has ever been observed.

TRIAL SUPPLIES ON APPLICATION TO
GLAXO LABORATORIES : 56 Osnaburgh Street : LONDON, N.W.1



"... to the busy practitioner who needs to conserve the last ounce of energy, the absence of all effort in gear changing must count a great deal in a busy day's work..." A.J., M.D.

"Your Self-Changing Gear has been a perfect revelation. I now come in from a busy round with no sort of feeling of fatigue as the result of stopping, starting, and changing gear so many times as I needs must do. The relief from this work as compared with the old form of gear change is really rather remarkable."

M.B., Ch.B.

Arrange a Trial Run—Have an Armstrong Siddeley for a round of visits and notice what a difference the self-changing gear makes. It is something you have been waiting for for years.

Prices from £275—All Six Cylinders

Collection of Overdue Accounts

ONE-THIRD of the accounts sent to us or collection are hopeless for a variety of reasons; they may be correctly described as "valueless."

The Annual Subscription and the exceedingly small Registration Fees are all we get to remunerate us for the vast amount of unprofitable work involved in trying to collect money from these impossible cases.

WITHOUT OFFENCE

Your visiting card marked "B" placed in an envelope will produce all information.

HOLLAND'S *Modified*
Natureform Shoes
are of special interest to Medical Women.

Made from new model lasts following the principle of the straight inner side, but all unnecessary room is eliminated—giving freedom of movement for all the bones of the feet—yet they are not ugly. You can recommend these productions to your patients with the assurance that they will enjoy better health and prevent malformation due to cramping of the metatarsal bones. Sample shoes sent for inspection to any member of the medical profession. Shoes specially made for any form of malformation.

Catalogue of "Natureform" Productions and Modified Natureform Shoes sent free on application.

The Goodness of Turkish Cigarettes

When the doctor says:—"Smoke fewer cigarettes!" patients reply sweetly "All right, I'll smoke more Royal Beauties!" and the doctors are not cross—they understand, for pure Turkish contains only about half the nicotine of ordinary Virginia tobacco and is therefore much better for you. And the linen filters in Royal Beauties do the rest. Some people fancy Turkish tobacco is doped. Royal Beauties are unconditionally guaranteed to contain nothing but absolutely pure undoped Turkish tobacco—so that's that

In three sizes: Turkish, 9/6, 10/6 and 12/6 a hundred

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. *Careful clinical, biochemical, bacteriological,* and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
[illegible] of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
[illegible] Superintendent at the Hospital.

Examination in which interested .....

County Borough of Blackburn.

WOMAN ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Blackburn invite applications from Women Practitioners of Medicine for the position of Assistant Medical Officer of Health, to act under the direction and supervision of the Medical Officer of Health, who is also School Medical Officer and Executive Tuberculosis Officer.

The salary will be £600 per annum, rising by annual increments of £25 to £700 per annum, inclusive.

Preference will be given to candidates with a Diploma in Public Health, and with special experience in Paediatrics, Obstetrics, and the treatment of Venereal Diseases in Women and Children.

Forms of application may be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and should be returned, together with copies of three recent testimonials, to the undersigned so that they will be received not later than the first post on Wednesday, May 27th.

Town Hall, Blackburn. May 8th, 1931. BRIGGS H. MARSDEN, Town Clerk.

£100 Grant for Post-Graduate

STUDY OF HOMOEOPATHY.—The BRITISH HOMOEOPATHIC ASSOCIATION (Inc.), 43, Russell Sq., London, W.C.1, invite applications from Graduates of Medicine of a British University, or the University of Calcutta, for a GRANT of £100 for a Post-Graduate Course of Study of the Principles and Practice of Homoeopathy, for six months, at the London Homoeopathic Hospital. Applicants must be under 30 years of age on March 1st, 1931. Closing date for applications July 1st, 1931. For further particulars apply to the Secretary at 43, Russell Square, W.C.1.

The Victoria University of MANCHESTER.

POST-GRADUATE MEDICAL COURSES.

An INTENSIVE POST-GRADUATE COURSE in OBSTETRICS is to be held at St. Mary's Hospital, Whitworth Street, Manchester, from Sunday, June 7th to June 14th, 1931. Fee for the Course 3 guineas.

Fee for residence, payable at St. Mary's Hospital, 4 guineas.

Further information may be obtained from the Dean of the Medical School.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

ABERGELE SANATORIUM. (262 Beds—210 Children, 52 Adults.)

APPOINTMENT OF ASSISTANT MEDICAL SUPERINTENDENT.

The *Public Health* Committee invites applications from qualified Medical Men of not over 35 years of age for the position of Assistant Medical Superintendent at the Abergele Sanatorium.

The Sanatorium is fully equipped with all modern requirements for the treatment of Tuberculosis in Children.

It is essential that every candidate shall have held resident *Surgical* and *Medical* appointments in a General Hospital, and have had experience in the treatment of pulmonary and non-pulmonary tuberculosis in children.

A knowledge of Orthopaedic work and experience in the administration of Anaesthetics is desirable.

Salary £600 per annum, inclusive of emoluments (house, coal, and light) valued at £92 per annum.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Superintendent, Abergele Sanatorium," must be addressed to the undermentioned only, and not to members of the Committee or Council, and must reach him not later than Saturday, May 30th.

The successful candidate will be under the general administrative control of the Medical Officer of Health, and will be required to pass a medical examination, to devote the whole of his time to the duties of his office, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, Manchester. May 11th, 1931. F. E. WARBRECK HOWELL, Town Clerk.

County Borough of Walsall.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners (single) for the post of Assistant Medical Officer of Health.

Salary £500 per annum, rising by £25 per annum to £700 per annum.

Candidates must possess a Diploma in Public Health or similar qualification.

The officer appointed will be required to devote his whole time to the duties of the office, which will consist mainly of Medical Inspection of School Children, Maternity, and Child Welfare work, and duties in connection with the treatment of Infectious Diseases. He will work under the direction of the Medical Officer of Health and will be required to reside at the Isolation Hospital when the requisite accommodation is provided.

Applications, on forms to be obtained from the undersigned, stating age, qualifications, training, and experience, together with copies of three testimonials, and endorsed on the envelope "Assistant Medical Officer," should be sent to me not later than May 30th.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Canvassing, directly or indirectly, will be a disqualification.

Council House, Walsall. May 15th, 1931. HERBERT LEE, Town Clerk.

County Borough of West Ham.

EDUCATION COMMITTEE.

APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICERS.

Applications are invited from fully qualified and registered Medical Practitioners for two appointments as Assistant School Medical Officers, under the direction of the School Medical Officer. The persons appointed will be required to devote their whole time to the service of the Education Committee.

Salary £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, allowance being made in respect of similar service under other Local Authorities in fixing the commencing salary in accordance with the scale agreed between the British Medical Association and the Local Education Authorities.

Applicants must have had not less than three years' experience since qualification and should have had previous experience in Medical Inspection and Treatment of School Children. A diploma in Public Health will be an advantage.

The appointments are designated posts under the Local Government and Other Officers Superannuation Act, 1922, and the successful applicants will be required to pass a medical examination as required by the Council for the purposes of that Act, and the statutory contributions of five per cent. to the Superannuation Fund will be deducted from their salary. In the event of the appointment of a woman, such appointment will be automatically terminated on marriage.

Canvassing members of the Education Committee or the Council, either directly or indirectly, will be considered a disqualification.

Forms of application, together with particulars of duties, may be obtained from the School Medical Officer, Town Hall, West Ham, E.15, upon receipt of a stamped addressed envelope, and should be returned to the undersigned not later than Saturday, May 30th.

Education Office, 95, The Grove, Stratford, E.15. May 13th, 1931. CHARLES E. CRANFIELD, Town Clerk and Education Officer.

Surrey County Council.

KINGSTON & DISTRICT HOSPITAL.

SECOND AND THIRD ASSISTANT RESIDENT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for the above-mentioned appointments, which will be for a period of six months in the first instance, but may be extended for a further term of six months.

Salaries will be at the rate of £300 per annum and £250 per annum respectively, together with full residential emoluments (rations, apartments, laundry, and attendance).

In the case of the Second Assistant Medical Officer, previous experience as House Surgeon in a General Hospital is essential.

The officers appointed will be required to assist at operations, to administer anaesthetics, to undertake casualty work, and such other duties as may be assigned to them by the Medical Superintendent.

Further particulars of the appointments may be obtained from the Medical Superintendent, Kingston & District Hospital, Kingston-on-Thames.

Applications, stating age, experience, qualifications, and nationality, accompanied by copies of not more than three recent testimonials, should be forwarded to the Divisional Public Assistance Officer, 29, Coombe Lane, Kingston-on-Thames, not later than Saturday, June 6th.

Canvassing, either directly or indirectly, will disqualify.

County Hall, Kingston-on-Thames. May 18th, 1931. DUDLEY AUKLAND, Clerk of the Council.

London Temperance Hospital,

Hampstead Road, N.W.1.

Applications are invited for the post of CASUALTY OFFICER (male). The appointment will be for a period of six months, at a salary of £120 per annum, and will date as from July 1st. Preference will be given to those who have held a resident post.

Candidates must submit applications, stating qualifications, age, etc., with copies of not more than three testimonials, by Friday, June 5th, addressed to the Secretary.

JEAN R. MURRAY, Secretary.

City of Carlisle.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council of the City and County Borough of Carlisle invite applications for the appointment of Assistant Medical Officer of Health, at a salary of £650 per annum, rising by annual increments of £50 to a maximum of £750 per annum. The duties of the appointment are principally those connected with the diagnosis and treatment of Tuberculosis and the medical inspection and treatment of school children, including Eye Work and Refractions.

Candidates must not be more than 40 years of age, and must be fully qualified and registered Medical Practitioners, holding the Diploma in Public Health or an equivalent qualification.

Candidates must either have held a previous appointment as Tuberculosis officer with the approval of the Minister of Health, or, subsequent to qualification:

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and
(3) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the City, and will not be allowed to engage in private practice.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the gentleman appointed will be required to pass a medical examination, and contribute 5 per cent. of his salary to the Superannuation Fund.

The Committee also employ a Female Assistant who is the Medical Officer for Maternity and Child Welfare, and undertakes part of the work of School Medical Inspection.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, and endorsed "Assistant Medical Officer of Health," must reach me not later than the first post on Thursday, June 4th.

Canvassing, either directly or indirectly, is prohibited.

Applicants may, if they desire, forward stencilled copies of their applications and testimonials to the members of the Selection Committee, a list of whose names will be supplied by the undersigned upon request.

FREDK. G. WEBSTER, Town Clerk.
Town Clerk's Office, Carlisle.
May 19th, 1931.

City of Cardiff.

LLANDOUGH HOSPITAL.

MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified Medical Practitioners (who have had experience of Hospital administration) for the appointment of Medical Superintendent of Llandough Hospital.

The Hospital, which is now in course of construction, is a Municipal General Hospital, where 340 beds will be provided in the first instance, under the management of the Health Committee.

Until the opening of the Hospital the Medical Superintendent will be engaged in its preparation and equipment, and will also act as Part-time Medical Officer of the City Lodge Poor Law Institution, where there are three Resident Assistant Medical Officers.

The salary will be £750 per annum, rising by biennial increments of £50 to £950 per annum, with emoluments (including house, with heating, lighting, and laundry) valued at £150 per annum.

The person appointed, who must devote his whole time to the duties of the post under the direction of the Medical Officer of Health, will be required to contribute 5 per cent. of his salary to the Superannuation Scheme of the Council, and for this purpose to pass a medical examination.

Applications, on forms obtainable from the Medical Officer of Health, City Hall, Cardiff, accompanied by copies of three recent testimonials, and endorsed "Medical Superintendent," must be sent to the Medical Officer of Health so as to reach him not later than Monday, June 8th.

City Hall, Cardiff.
May 18th, 1931.

CECIL G. BROWN, Town Clerk.

The Royal Alexandra Infirmary,

PAISLEY.

RESIDENT HOUSE SURGEON required for six months. Honorarium at the rate of £100 per annum, with board, washing, etc. Apply to Senior Resident House Surgeon.

Administrative County of LONDON.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications for appointment as RESIDENT MEDICAL SUPERINTENDENT in the Public Health Department for duty at HAMMERSMITH HOSPITAL, Ducane Road, Shepherd's Bush, W.12. The duties also include those of Medical Officer and Acting Master of Hammersmith Institution.

The person appointed will be required to act under the direction of the Medical Officer of Health and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the London County Council.

The salary is £950 a year, rising by annual increments of £50 to £1,200 a year. £100 a year extra will be paid so long as the officer is acting as administrative and medical head of the Institution. An unfurnished house or quarters, free of rates, taxes, or water charges, will be provided, valued provisionally at £100 a year.

Candidates must be duly qualified Medical Practitioners of at least five years' standing, and produce evidence of having held the appointment of House Physician or House Surgeon in a public General Hospital, and of having had experience of Hospital administration.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1, and must be returned by June 8th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.
The County Hall,
Westminster Bridge, S.E.1. May, 1931.

County Borough of West BROMWICH.

HALLAM HOSPITAL.

RESIDENT HOUSE SURGEON.

Applications are invited from fully qualified male registered Practitioners (single) for the above appointment.

The appointment is for twelve months, but either party may give six weeks' notice terminating the engagement. The Hospital has 474 beds, and is equipped with up-to-date Special Departments. There is a visiting staff of eight Consultant Physicians and Surgeons.

Preference will be given to applicants with previous Hospital experience.

Salary £250 per annum.

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Wednesday, June 10th.

Town Hall, West Bromwich.
May 16th, 1931.

ALFRED WICKHAM, Town Clerk.

The Hospital for Sick Children,

Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on July 1st.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 1st, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried, and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, June 3rd, at 5 p.m. precisely.

Forms of application and copies of the Rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES MACKAY, Secretary.
May, 1931.

Edinburgh Hospital for Women AND CHILDREN,

Whitehouse Loan, EDINBURGH. (50 Beds.)

Applications are invited from qualified Medical Women for the post of HOUSE PHYSICIAN at the above Hospital. The appointment is for six months from July 1st, with board, residence, and laundry. Honorarium at the rate of £80 per annum.

WITH SUPPLEMENT

No. 3673 SATURDAY, MAY 30, 1931 Price 1/3

The "Allenburys"

"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

BRITISH BRITISH

Elastoplast

(Patent 253,527)

THE ORIGINAL & FINEST ELASTIC PLASTER

The cure of Varicose Ulcer by means of Elastoplast Bandages is now practised in nearly every Hospital in the British Isles, and 100% cure of cases is achieved.

In certain cases of Varicose Veins where on account of systemic disease, or the patient's timidity, a curative course of injection cannot be given, then the veins can be kept obliterated by Elastoplast.

Elastoplast is also extensively used for general surgical and orthopaedic work.

As a support for varicose veins, sprains, strains, dislocations, after-treatment of fractures, weak joints, flat or dropped foot, etc., Elastoplast is unequalled.

Manufactured from the finest yarns, Elastoplast is the only Elastic Plaster having the correct degree of elasticity, thus ensuring perfect compression and support.

Woman patient aged 55. After 12 weeks' treatment. After a further 2 weeks.

The only treatment consisted of Elastoplast Bandages, changed weekly at first, and later fortnightly.

Other Elastoplast Specialities include:—Finger Dressings, Wound Squares, Wound Strips, Boil Dressings, Eye Dressings, Vaccination Dressings, etc., all on the pliable Elastoplast base, with medicated pads. Elastoplast will reduce your Dressings Accounts, save you valuable time, increase the efficiency of the injured person, and, moreover, ensure cleanliness.
Also—VISCOPASTE BANDAGES (improved Unna's Paste Type), Adhesive Gelatine Bandages.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2/6 (Overseas postage extra) by the manufacturers:

T. J. SMITH & NEPHEW, Ltd.

HULL. LONDON. GLASGOW. MANCHESTER.

Enquiries to—Dept. B, 42, Tavistock Square, London, W.C.1.

ELASTOPLAST MAY BE OBTAINED FROM YOUR USUAL SURGICAL SUPPLY HOUSE.

CLINICAL CHEMICAL PATHOLOGY
F. S. FOWWEATHER, M.D., M.Sc., D.P.H. 18 Illustrations. 8s. 6d. Post. 4d.

THE PRACTICE OF REFRACTION
W. STEWART DUKE-ELDER, D.Sc., M.D., F.R.C.S. 203 Illustrations. 12s. 6d. Post. 6d.

MATERNAL MORTALITY
HENRY JELLETT, M.D., F.R.C.P.I., late Master, Rotunda Hospital, Dublin. 15s. Post. 6d.

DISEASES OF THE BLOOD
A. PINEY, M.D., M.R.C.P., Research Pathologist, Cancer Hospital. 20 Illustrations, including 6 Coloured Plates. 12s. 6d. Post. 6d.

A HANDBOOK OF MIDWIFERY
RICHARD E. TOTTENHAM, M.D., F.C.O.G., F.R.C.P.I., Professor of Obstetrics, University of Hong-Kong. 10s. 6d. Post. 6d.

THE "RECENT ADVANCES" SERIES

[illegible] treatment change so quickly that such publications as the 'Recent Advances' Series are invaluable to the general [illegible] as he usually is, for post-graduate study."—BRITISH MEDICAL JOURNAL.

[illegible] Advances' Series published by Messrs. J. & A. Churchill meets a want in medical literature by providing a concise, [illegible] detailed summary of developments in the theory as well as in the practice of the various specialities into which medicine [illegible] very steadily."—EDINBURGH MEDICAL JOURNAL.

RHEUMATISM
[illegible] ANTON, M.D., F.R.C.P., and [illegible] SCHLESINGER, M.D. 25 [illegible]

CHEMOTHERAPY
[illegible] LINDLAY, O.B.E., M.D. 15 Illus.

PREVENTIVE MEDICINE
[illegible] BOSTAM, M.C., M.D. 30 Illus.

SURGERY
[illegible] GRAHAM, F.R.C.S. 2nd Ed. [illegible]

OPHTHALMOLOGY
[illegible] DUKE-ELDER, D.Sc., M.D., F.R.C.S. [illegible] Plates. 110 Figs. 12s. 6d.

DISEASES OF CHILDREN
[illegible] EATSON, D.S.O., D.M., and W. G. [illegible] M.D. 2nd Ed. 20 Plates. 34

TROPICAL MEDICINE
[illegible] LEONARD ROGERS, C.I.E., M.D., [illegible] F.R.C.P., F.R.S. 2nd Ed. [illegible]

BACTERIOLOGY
[illegible] DOBELL, M.B., B.Ch. 24 Illus.

MICROSCOPY, Biological Applications
A. PINEY, M.D., BASIL GRAVES, M.C., E. W. MACBRIDE, F.R.S., H. R. HEWER, and E. C. BARTON-WRIGHT. 83 Illus. 12s. 6d.

OBSTETRICS & GYNAECOLOGY
ALECK W. BOURNE, M.B., F.R.C.S. 2nd Ed. 67 Illus. 12s. 6d.

NEUROLOGY
W. R. BRAIN, M.D., and E. B. STRAUSS, B.M. 2nd Ed. 39 Illus. 12s. 6d.

MEDICINE
G. E. BEAUMONT, D.M., and E. C. DODDS, M.A.O., M.D. 5th Ed. 49 Illus. 12s. 6d.

FORENSIC MEDICINE
SYDNEY SMITH, M.D., and J. GLAISTER, Jnr., M.D. 66 Illus. 12s. 6d.

PLANT PHYSIOLOGY
E. BARTON-WRIGHT. 51 Illus. 12s. 6d.

CARDIOLOGY
C. F. TERENCE EAST, M.D., F.R.C.P., and C. W. CURTIS BAIN, M.C., M.B. 2nd Ed. 10 Plates. 62 Figs. 12s. 6d.

PULMONARY TUBERCULOSIS
L. S. T. BURRELL, M.D., F.R.C.P. 2nd Ed. 32 Plates. 17 Figs. 12s. 6d.

ENTOMOLOGY
A. D. IMMS, D.Sc., F.R.S. 84 Illus. 12s. 6d.

RADIOLOGY
PETER KERLEY, M.B., B.Ch., D.M.R.E., Assist. Radiol., Westmin. Hosp. 120 Illus. 12s. 6d.

BIOCHEMISTRY
J. PRYDE, M.Sc. 3rd Ed. 42 Illus. 12s. 6d.

ANATOMY
H. WOOLLARD, M.D., B.S. 4 Col. Plates. 73 Figs. 12s. 6d.

PHYSIOLOGY
C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S. 4th Ed. 113 Illus. 12s. 6d.

HAEMATOLOGY
A. PINEY, M.D. 3rd Ed. 6 Col. Plates. 18 Figs. 12s. 6d.

PSYCHIATRY
H. DEVINE, O.B.E., M.D., F.R.C.P. 4 Illus. 12s. 6d.

THE PSYCHONEUROSES
MILLAIS CULPIN, M.D., F.R.C.S. 12s. 6d.

ANALYTICAL CHEMISTRY
C. A. MITCHELL, D.Sc., M.A., F.I.C. Vol. I, Organic. 6 Plates, 17 Text-figs. 12s. 6d. Vol. II, Inorganic. 12s. 6d.

Recent Advances' Series has established such a high standard of excellence that one expects much in any book included MEDICAL PRESS.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

Announcement of the British Medical Association

• British
• Medical
• Journal

EVERY special issue of the British Medical Journal may be expected to provide material of interest to a large proportion of the profession. The next Special Number, to be published on June 6th, will include among its principal contents two recent lectures of much importance, one of them being accompanied by coloured illustrations on art paper plates. Original articles and clinical memoranda, covering a wide field of practice, will also be published together with full information about the Annual Meeting of the British Medical Association to be held at Eastbourne in July.

Mention may be made here of the carefully compiled advertisement sections in the Special Number. Readers have, at all times, shown their appreciation of advertisements appearing in these columns, and it is well known that their practical support has contributed to the high regard in which the British Medical Journal is held throughout the Advertising world. The advertisements published week by week constitute, in effect, an exhibition of current medical and surgical requisites which the doctor mindful of his obligations cannot fail to examine, for this is the recognized channel through which information about the accessories to practice may be obtained.

• Special
• Number
• June 6th

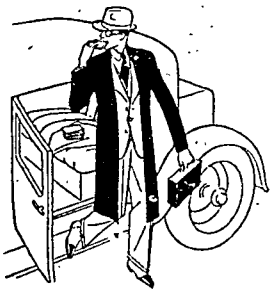
The forthcoming Special Number replaces the usual issue due to appear on the same date, and it will be sent to all members of the British Medical Association in the customary way. Despite the higher cost of production, due to reproductions in colour, there will be no increase in the normal charge of 1s. 3d. per copy made in respect of copies purchased by non-members.

• *Enquiries concerning the Journal should be addressed to:—*

The Manager, British Medical Journal,
B.M.A. House, Tavistock Square, London, W.C.1

The same old round . . .

but what a treat to come home to!



. . . so many patients to visit that you only have time to snatch a sandwich in the car at lunch time. But if, at the end of the day, there was a long, cold drink to come home to, and the sort of perfectly served meal that comes cool and fresh and appetising from a Frigidaire . . . what a difference! . . . Fill in the coupon and see how easily you *can* afford a Frigidaire.

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric refrigerator. Here are just a few of them.

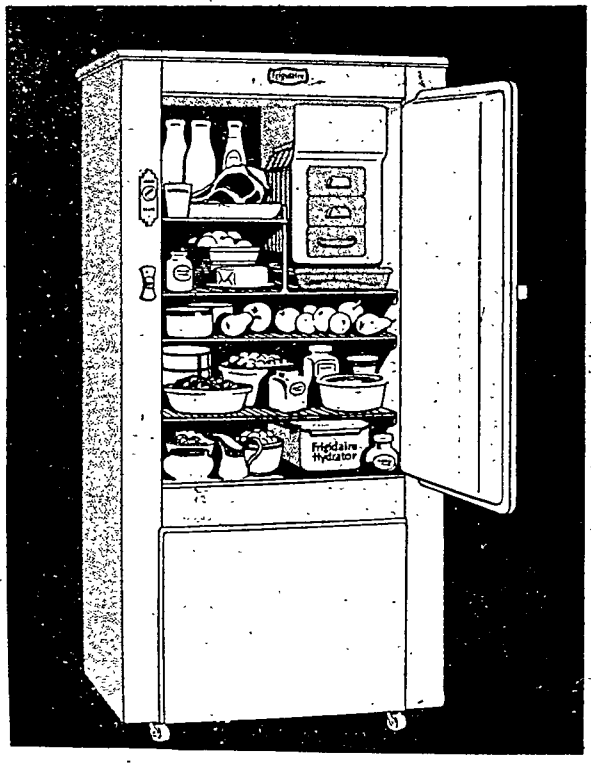
The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.

●

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

●

The automatic feature of Frigidaire is invaluable. The safety of your food does not depend on a maid's vigilance. Frigidaire maintains a dry cold that is *always* under 50° — the only safe temperature for food.



Practical, flat top makes a useful shelf.

○

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc. Even wilted vegetables will regain their crispness here in a few hours.

●

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

●

Frigidaire Cabinets are all white porcelain-on-steel—the finest durable finish it is possible to have. And easily kept clean by just a rub with a damp cloth.

●

The new Frigidaire is quiet—you can't hear it start, stop or run.

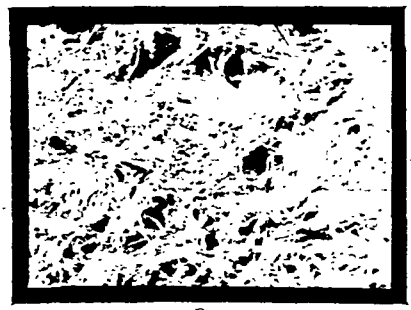
A NEW departure in CIGARETTE manufacture

The Introduction of the Filter-Tip

Under the name 'du Maurier,' so called by courtesy of Sir Gerald du Maurier, for whom the cigarettes were originally made, a new departure in cigarette manufacture has been introduced. It consists of a cigarette, containing natural Virginia leaf of high quality, at the end of which is a filter-tip, on behalf of which claims are made of interest to the medical profession. They may be summarised as follows :



Magnified view of cellulose fibre (contained in the filter-tip). BEFORE SMOKING.

Magnified view of the cellulose fibre (contained in the filter-tip). AFTER SMOKING.

I. The filter-tip is selective in its action and while permitting the full passage of all the desirable constituents, shows a high capacity for retaining both the pyridine bases and non-volatile bodies, which undoubtedly form the principal source of throat irritation.

II. Unfiltered smoke is as dangerous as unfiltered water and as irritating as dust-laden air. The filter-tip effectively purifies tobacco smoke from harmful irritant and acrid substances which are inevitably formed when tobacco leaf, even of the finest-quality, is burned.

III. By the introduction of the filter-tip the palate loses nothing, but the voice and throat gain immeasurably as the irritants are held in check without impairing the flavour or delicate character of the smoke. This is the central advantage to be gained from the filter-tip.

IV. Cigarettes containing this filter-tip will be welcomed both by the medical profession and the public as a valuable means of preventing "smoker's cough" and other adverse effects on the pharynx, larynx or general health, traceable either directly or indirectly to the irritants and acrids in tobacco smoke.

V. They constitute the only safe form of smoking for those predisposed to, or suffering from, pharyngitis, laryngitis, or any form of bronchial or respiratory affection. They are invaluable in cases of gastric trouble due to tobacco tar.

From THE BRITISH MEDICAL JOURNAL
April 18th, 1931, page 692.

The aim of this ingenious filter is to trap the irritating pyridine derivatives and other non-volatile bodies while permitting free passage of the agreeable volatile constituents of tobacco smoke.

From THE LANCET'S report,
January 24th, 1931, page 194.

We have tested these cigarettes and find them to be cooler and less irritating to the mucous membrane than ordinary cigarettes of good quality without the filter-tip.

The filter-tip . . . retains bodies which are generally held to be the principal cause of throat irritation. Additional advantages of the filter-tip comprise protection of the lips, teeth and fingers from unsightly stain, and prevention of fragments of tobacco from getting into the mouth.

The du Maurier cigarettes may be regarded in every way as satisfactory, and they constitute a distinct and hygienic advance in the marketing of cigarettes.

du MAURIER *Virginia*

'du Maurier' Virginia Cigarettes at 20 for 1/-, 50 for 2/6, can be obtained from Peter Jackson, 217, Piccadilly, London, W.1, but we would prefer you to buy them from your tobacconist.

Cod-Liver Oil Cream

This ethical preparation is particularly acceptable to children. It may be prescribed with confidence that good results will be obtained.

Children take it readily, even where the usual difficulty has been experienced in inducing them to take other forms of Cod-Liver Oil. They rapidly respond to its nutritive and strengthening influence.

The Cream contains 50% of recently refined Cod-Liver Oil of high vitamin content. The fresh eggs used in the making enhance the value of the preparation as a nutrient. The Emulsion is perfect (vide *The Lancet*, Jan. 4th, 1930), rendering the assimilation easy, even in cases where digestion is weak.

The fact that it is freshly prepared every week ensures freedom from loss of vitamin efficiency of the oil, due to storage or exposure to sunlight.

The preparation is endorsed by many members of the Medical Profession.

4/-, 7/-, and 10/-, post free.

Supplied by return of post to ensure freshness.

SPECIALLY VALUABLE IN MIDWIFERY

10 TIMES STRONGER THAN LYSOL

MOND STAFFORDSHIRE REFINING CO., LTD., ABBEY HOUSE, WESTMINSTER, S.W.1

Intestinal Debility

"Cristolax" is worthy of careful trial in all cases of constipation. It is composed of 50 per cent. of the purest medicinal paraffin in combination with 50 per cent. of "Wander" Dry Malt Extract. The paraffin content acts mechanically for expelling the fæces, while the high diastatic property of the malt extract assists digestion and improves nutrition.

Where the patient has been accustomed to use an ordinary laxative regularly it is recommended that this should be continued in diminishing doses with the "Cristolax" treatment. It is quickly found that the "Cristolax" method of intestinal lubrication will alone ensure adequate and regular defecation.

Patients highly approve the pleasant flavour of "Cristolax," the complete absence of oiliness and its cleanly form.

"CRISTOLAX"
BRAND
MALT EXTRACT WITH PARAFFIN
Lubricant-Laxative-Nutrient-Digestive

A supply for Clinical trial sent free on request.

Of all Pharmacists, in bottles at 3d & 2- each.

HORLICK'S

HORLICK'S MALTED MILK is a food which can be usefully employed by the physician, not only in acute illnesses and during convalescence, but in the many chronic conditions of ill-health, which are favourably modified by correct dieting. In heart diseases generally, and in myocardial failure particularly, HORLICK'S acts as a "stimulant" and gives a maximum of energy with a minimum of effort. It is a muscle food, and lessens the strain upon the heart by reason of both its ease of digestion and its tendency to correct constipation. If the intake of fluid has to be limited, HORLICK'S MALTED MILK will be found palatable and agreeable even in a concentration twice the normal strength. The mixed carbohydrates—lactose, maltose and dextrin—in HORLICK'S MALTED MILK give it a value in nephritis. Carbohydrates are usually well utilized in this condition and, being "protein-sparers," afford rest to the inflamed structures. As a diet in gout and other disturbed metabolic conditions in which purin bodies are contraindicated, HORLICK'S can be safely recommended, since it is purin free.

Proverbs Up-to-date No 6

KEEP YOUR POWDER DRY

Manufacturers of Tooth Powders are accustomed to advance strong arguments for the use of dry powder as a cleanser of the mouth and teeth. It cannot be denied that a powder, if not too abrasive, forms an excellent polishing agent. And for this reason, a powder compounded of specially selected materials of exact quality and texture forms the polishing agent in Gibbs Dentifrice. It loses none of its efficiency by being combined with a saponaceous base. Indeed the saponaceous base of Gibbs Dentifrice tends to counteract any possible harshness, adds materially to the cleansing efficacy, and dispenses with one of the greatest disadvantages that a raw Powder exhibits; namely, wasteful messiness.

That is why Gibbs Dentifrice has won the wholehearted support of leading Medical authorities. By providing the public with a thoroughly safe and efficient dentifrice, and by giving it the widest publicity in the national press, Gibbs makes a valuable contribution to the cause of preventive dentistry. But in all Gibbs propaganda, the indispensability of the Doctor and Dentist is made perfectly clear. In fact, the most frequently recurring phrase in Gibbs Advertising is "Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day.

G.BBS MOUTHWASH

A Peroxide Mouth Wash in Powder form. A new Preparation by Gibbs that has met with instant success. Gibbs Mouth Wash produces Oxygen in the mouth, which has a wonderfully efficient cleansing and antiseptic effect; and definitely purifies the breath. Although intended for twice daily household use, Gibbs Mouth Wash provides an excellent and safe mouth wash for use following extractions.

Gibbs Dentifrice

Local Anæsthesia in Surgical Practice

CERVICAL ADENITIS.

Typical Case.

R. H., aged 19 years.

Diagnosis: Bilateral cervical adenitis (tuberculous).

Operation: Block dissection of the neck (right side).

Anaesthesia: Local infiltration, cervical neck block 160 c.c. of a 0.7 of 1 per cent. Novocain-Adrenaline solution were used. A complete block dissection was made under perfect anaesthesia. On October 3rd, 1919, the patient re-entered the hospital for a dissection of the opposite side and the same procedure was carried out.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Liver Therapy in ANAEMIA

The haemopoietic value of liver manifests itself clinically in a most rapid and convincing manner, and it is now recognised that various fractions exist, having separate and distinct characteristics.

HEPATEX

This is the liquid extract of liver made at Evans' Biological Institute. Introduced for the treatment of pernicious anaemia, in which it has been proved highly satisfactory, its success in the severe secondary anaemias has been so pronounced as to warrant investigation. It is now found that HEPATEX contains the full Vitamin B complex, the various components of which must assuredly be of great therapeutic value, and it may well be that its usefulness in the secondary anaemias is due to this factor. HEPATEX is prepared and concentrated so that a teaspoonful dose contains the full therapeutic principles of 2 ozs. of fresh liver.

Issued in 4 oz. bottles, 12/6 each.

Prepared at Evans' Biological Institute, Higher Runcorn, Cheshire.

ENLARGED COIN OF THEODORIC THE GREAT, KING OF THE GOTHS AND RULER OF THE ROMANS.

Theodoric, son of Theudemir, king of the Ostrogoths, was brought up at the court of the East Roman emperor at Constantinople, having been surrendered, at the age of eight by his reluctant father, as hostage for the good faith of the Ostrogoths in a renewed alliance with the empire. During his years of honourable captivity, he became imbued with Graeco-Roman civilisation. Returned to his own people, he was made king on the death of his father. In 488, he led the Goths, in the name of the emperor Zeno, into Italy and in 493 became "Governor of the Goths and Romans" in place of the defeated Odovacar—like himself a Teuton. During his reign of thirty-three years Theodoric laboured to restore degenerated Italy; he succeeded in rousing in her a sense of nationality and in placing her in a position of political dignity. The system he built up by the sheer force of his lofty personality brought a generation of happiness and prosperity to Italy. For fourteen years Theodoric also governed the Visigoths in Spain conjointly with their young king Amalaric.

DATE: Theodoric, rule in Italy A.D. 493-526

COPYRIGHT

What three doctors say about Odol

1. STOMATITIS

"I have often recommended Odol to patients suffering from Stomatitis and have found it very efficacious."

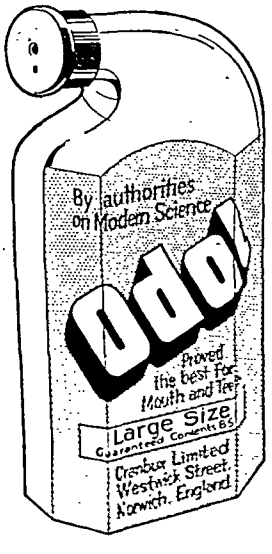
....., M.R.C.S.Eng., L.R.C.P.Lond.

2. NOSE WORK

"I use a solution of Odol for all nose work, washing out the antrum and sinuses, etc. It is excellent and a soothing antiseptic."

....., M.D.

3. ZYMOTIC DISEASES



"It is most excellent in septic conditions of the mouth such as one finds in the zymotic diseases."

....., M.C., L.R.C.P., M.D.H.

Not only is Odol definitely antiseptic—not only does it destroy disease germs of the mouth and throat—not only does it check the growth of bacteria for hours after use—but it is perfectly safe. Non-toxic, non-caustic, and non-acid, Odol does not injure the teeth or the mucous membrane of the mouth.

Samples and literature will gladly be sent to any member of the Medical Profession on application to:

The Hume Lectures
ON
HAEMOLYTIC ICTERUS*

BY
LORD DAWSON OF PENN, P.C., M.D., D.C.L.
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN IN ORDINARY TO H.M. THE KING; EXTRA PHYSICIAN TO THE LONDON HOSPITAL

LECTURE I

The disease haemolytic jaundice has an interest beyond itself, in that its features bring us in contact with the problems of the origin and destiny of blood and bile, and so with the functions of marrow and liver and spleen—difficult though fruitful territories for exploration. For the purpose of these lectures it is well at the outset to recall briefly our present knowledge of jaundice. It is now established that, unlike bile salts, bile pigment is in the higher mammals formed in greater part outside the liver. The later stages of this knowledge have been gained as follows.

ORIGIN OF BILE PIGMENT

In 1913 Whipple and Hooper[1] found that in dogs in which the liver had been isolated from the general circulation, bile pigment accumulated in the blood, and jaundice followed. From 1921 onwards Mann and his co-adjutors,[2 3 4 5] by brilliant technique, were able to show in a succession of researches that after complete removal of the liver in dogs bilirubin appeared in the blood plasma. If from one dog the liver was removed, and in another dog the common bile duct was ligated and the gall-bladder removed, within three hours in each case bilirubin appeared in the plasma. Thus the origin of bilirubin is extrahepatic.

Next it was found that even after removal of all the abdominal organs, bilirubin made obvious appearance in the plasma. Further, by the delicate spectrophotometer[5] the bilirubin contents of the arterial and venous blood travelling to and from a limb, the inside of a long bone, and the kidneys and the spleen, could be compared. In the case of the limb and the kidney there was no difference, whereas in the case of the marrow and spleen the venous blood contained more bilirubin than the arterial blood. The inference was therefore clear that the marrow and spleen are sites for the formation of bilirubin. Of these two sites the marrow, in the dog, was considered the more important for two reasons; first, the excess of bilirubin was greater in its veins compared with that of the splenic vein, and secondly, bilirubin still appeared in the plasma after complete excision of the abdominal organs. At a later date[6] the blood leaving the liver was shown to have a bilirubin content in excess of that of the arterial blood entering the liver. The above results have been confirmed by Rich[7 9] and other observers.[10] Similarly, investigation in man demonstrated the formation of bilirubin outside the liver. Thus it was shown by van den Bergh and Snapper[11] in 1915 that the blood from the splenic vein had a higher bilirubin content than the blood from the splenic artery. Rich and Reinhoff[12] came to similar conclusions.

Is it not notable that, as far back as 1847, Virchow[13]—a master-mind alike in science and statesmanship—after observing that haematoidin was found in old blood clots, concluded that bile pigment could be formed outside the liver, and it is now known that haematoidin and bilirubin are the same substance?[14] Lepehne,[15] Rosenthal,[16] and other Continental workers, however, are not so far convinced that the polygonal cell of the liver plays no part in the formation of bilirubin.

THE RETICULO-ENDOTHELIAL SYSTEM

To Aschoff[17] we owe the interesting conception of specialized endothelial cells, mesoblastic in origin, in some places woven together into more or less defined formations and in others existing as isolated units like the British Empire, a fabric scattered and loose in formation yet with unity of purpose. These cells lie along the venous sinusoids and capillaries of the bone marrow, spleen and liver, and the lymph sinusoids of lymphatic glands. They also appear singly throughout the connective tissue of the body. In response to the needs of the organism this system of cells is capable of a considerable hyperplasia and even of extension—for example, pleural cells will take on the function of these specialized cells (macrophages). The property of imbibing intra-vitam stains possessed by these cells has been beautifully illustrated by the work of Cappell.[18] By their phagocytic power they probably play a part in the defence against infections, and it is now established they are sites

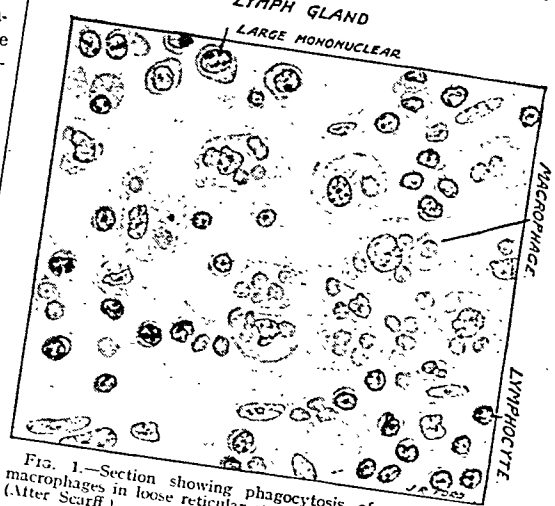

FIG. 1.—Section showing phagocytosis of red cells by macrophages in loose reticular structure of lymphatic gland. (After Scarff.)

where haemoglobin is disintegrated and pigment is formed (Fig. 1). McNee[19] made the suggestion (1913) that in these endothelial cells bilirubin had its origin.

Isolated units of wandering endothelial cells in the periphery of old blood clots have been shown by Rich and others[12] to imbibe the haemoglobin and to convert it into bilirubin within their protoplasm; further, Rich[20] has demonstrated the formation of bilirubin from haemoglobin, even in tissue culture cells. Large numbers of such endothelial cells exist as textures within the spleen and marrow. In the liver this reticulo-endothelial system is represented by the Kupffer cells, which are extensions of the endothelial lining of the vascular capillaries. These cells take up the haemoglobin from the blood stream and split it into bilirubin and haemosiderin.

In birds, where the spleen is very small and the liver large, the Kupffer cells are prominent, and play an important part in the conversion of haemoglobin into bilirubin; but in the higher mammals the Kupffer cells play but a small part in this conversion, though after splenectomy they increase in formation and function.

It is thus clear that bilirubin formed in the reticulo-endothelial system is carried to the liver by the portal vein. A diagrammatic representation of the liver is

* Delivered before the Northern Counties and Newcastle-upon-Tyne Medical Society on February 19th and 26th.

shown in *Fig. 2*. In each lobule it is excreted from the portal venous sinusoid by the polygonal cells into the bile capillary. Put in other words, the liver cells excrete the bile pigment and secrete the bile acids into the bile capillary. In the polygonal cells the threshold of excretion is normally a low one, so that the bilirubin content of the blood is small—namely, 0.2 unit to 0.4 unit (van den Bergh). If, however, the bilirubin content of the incoming blood is too high, or if the liver cells are damaged (for example, by some diseased process), or if there is a combination of these two conditions, there is an inadequate excretion of bilirubin, which banks up in the portal blood and the unexcreted portion passes thereby via the hepatic vein into the general circulation. In the strict sense the unexcreted portion does not enter the liver, but is retained in the blood —"retention jaundice." If the plasma bilirubin is duly excreted into the biliary capillaries, but there is some obstruction to the flow of the bile into the intestine, then there is a back pressure, and the whole bile migrates (regurgitation) from the overfilled canaliculi into the tissue spaces, and so into the periportal lymphatics and into the venous sinusoids, and so into the central intralobular vein—"regurgitation jaundice." The classification into retention and regurgitation jaundice suggested by Rich[21] would thus appear to be the most comprehensive.

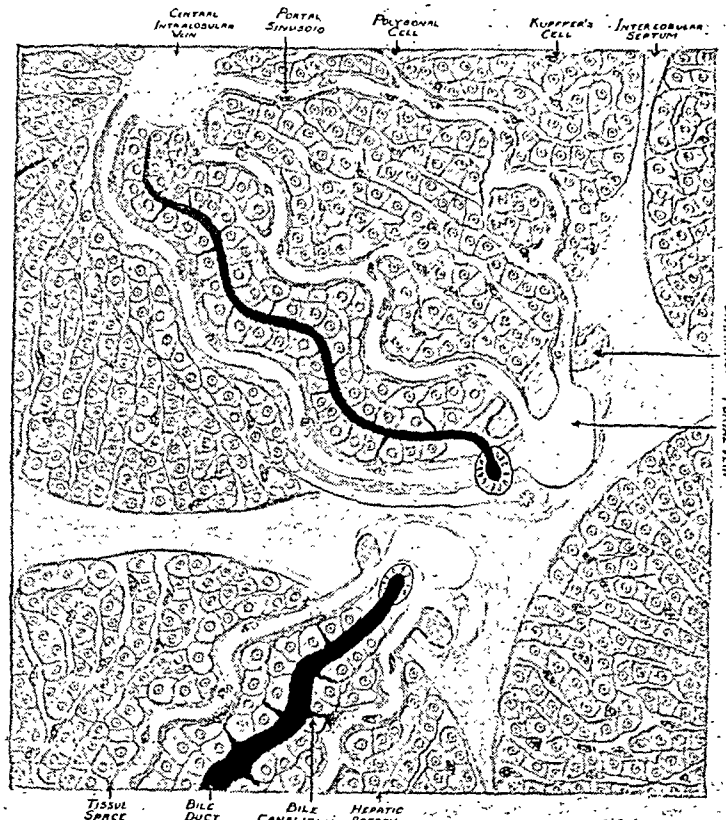

FIG. 2.—Diagrammatic representation of liver lobules, showing relation of portal sinusoids to polygonal cells. Lower portion of diagram shows the distended bile duct as found in obstructive jaundice, with rupture of bile canaliculi into lymphatic tissue space and sinusoid.

HYPERBILIRUBINAEMIA

There are thus two forms of hyperbilirubinaemia: one in which bilirubin of the plasma has first passed through the liver cells, and has perhaps been modified thereby, and the other in which the bilirubin has passed direct into the circulation without contact with the liver cells. In practice the two forms may coexist. Jaundice is an outward and visible sign of excess of bilirubin in the blood. If that excess is marked, jaundice there must be. There may, however, be a moderate degree of this hyperbilirubinaemia, and one that may be long-continuing without jaundice being apparent, given a low threshold and good function of liver cells and a free biliary tract.

The detection and measurement of bilirubinaemia have become an accurate procedure, thanks to the van den Bergh tests and the spectrophotometer. The latter is the more delicate, the former the more easily applied, method.

The van den Bergh test not only gives a measure of the amount of bilirubin present, but enables discrimination to be made between bilirubin which has, and bilirubin which has not, been excreted by the liver cells into the biliary ducts. The former gives a direct or immediate reaction, and the latter an indirect or delayed reaction. The indirect reaction represents bile pigment retained in the circulation, and the direct reaction bile which has filtered back into the circulation either through back pressure in the biliary tree or on account of serious damage to the liver cells. Bile derived either from the common duct or from the gall-bladder will give the direct reaction. Sometimes a so-called diphasic reaction occurs which is intermediate between the direct and indirect reactions. This diphasic reaction indicates that bilirubin is present in excess, but does not define the mode of its entry into the blood. In health the bilirubin content of the blood varies between 0.2 and 0.5 unit. (*N.B.*, 2 units = 1 mg. bilirubin per 100 c.cm.)[22] Allowing for exceptions, the van den Bergh reaction is a valuable guide to the origin and amount of a bilirubinaemia. The difference between the indirect and the direct reactions may be explained by assuming that the bilirubin undergoes some change in passing through the liver cells, but a more probable explanation is that in the retention type of jaundice the bilirubin is held by the plasma, whereas in the regurgitation jaundice the excess of bile salts prevents this linkage, and the bilirubin exists in a free state.[23 24 25] A colour comparison of the serum with a standard potassium dichromate solution has been used to assess the degree of bilirubinaemia.[26 27 28] This gives quantitative figures (icterus index), but no information on the type of jaundice, and does not discriminate between small amounts of bile pigment in the serum and other colouring substances, such as are found in carotinaemia.

I will now pass to the consideration of haemolytic icterus (acholuric jaundice), this study of which is based on forty cases.*

RETENTION JAUNDICE

The jaundice, if haemolytic, is never deep; it may be obvious as a lemon colouring of skin and conjunctivae, or may be confined to tinting of the conjunctivae only; again, in some cases it is absent. It is a variable feature; it will ebb and flow or come and go, though the disease persists. Chilling of the body will provoke its increase. Further, the time of its first appearance varies. Though commonly manifest in infancy, its first appearance may be delayed for several years; thus in this series some eleven

* Portions of this study have been communicated to meetings of the Association of Physicians, but have not been reported.

cases showed jaundice for the first time at various ages—for example, 6, 12, 18, 23, 44—though splenomegaly, anaemia, and hyperbilirubinaemia, and probably increased fragility, were previously present.

Of even greater interest is the fact that in some cases jaundice is absent. That was so in four cases of this series. Thus in the family, "Tope," to be described below, two members have had no jaundice, although one of these died of acute anaemia at the age of 3½; whereas two other members of the same family have had a yellow colour since birth. In a family reported upon by Gotsky and Isaac,[29] three children had increased fragility, splenomegaly, and anaemia, but no jaundice, whereas with their father and grandmother jaundice was an outstanding feature. Nor do the jaundice and the anaemia show correlation in intensity, but appear to be variants of the same haemolytic process. In such of these cases in which the van den Bergh test has been recorded, the indirect reaction, though always positive, does not appear to be proportional to the degrees of anaemia or fragility.

The amount of bilirubin in the blood, registered by the van den Bergh test, will depend not only on the grade of haemolysis, but as much, if not more, on the excreting capacity of the liver cells. The threshold of these cells is low, and even if the haemolysis is considerable, and the delivery of the bilirubin by the portal veins high, the rate of excretion by the liver cells keeps only a short distance behind. In fact, the distance behind may be so short in some cases that no jaundice is apparent.

Thus in one case there was a high fragility, 0.7 to 0.4, a red cell count of 2,920,000, reticulocytes 6.5 per cent., indirect van den Bergh reaction 3.0 units, and yet only a tinge of jaundice—that is, a considerable haemolysis, a moderate increase of plasma-bilirubin, and only a slight icterus. In other words, excretion by the liver cells into the canaliculi was not far from keeping pace with the larger supply.

It follows that in haemolytic icterus there should be an increased quantity of bilirubin passing from the bile ducts into the intestines, where it would be reduced to urobilin; such increase of the faecal urobilin (stercobilin) does occur. An interesting illustration of this fact is afforded by duodenal intubation in icterus neonatorum. Hess[30] found that where jaundice was marked, the bile in the duodenum was plentiful, but in infants not jaundiced it was scanty or absent.

The urobilinuria so usual in haemolytic icterus is accounted for by this increased amount of urobilin in the intestine. The absence of bilirubin from the urine is more difficult to explain. It has been suggested that its fixation to the blood plasma prevents the kidney cells from excreting it.

Regurgitation Jaundice

The increased production of bilirubin from the blood in haemolytic icterus will surcharge the liver with this product and predispose to the throwing down of pigment. When this occurs biliary colic or dyspepsia and backpressure jaundice are likely to appear, and the van den Bergh test will give either a direct or a biphasic reaction. In this series thirteen patients developed symptoms due to the gall-bladder or biliary ducts, and with four of them gall colic was the first event in the clinical history, the yellow tint of the haemolytic jaundice having been previously absent or so faint as to escape notice.

The Spleen

The spleen as a rule is palpable and often considerably enlarged; the enlargement is liable to vary. According to Gänsslen,[31] in as many as 30 per cent. of cases the spleen is not palpable, but it may still be enlarged in an upward or backward direction. A palpable spleen is often the means of putting the clinician on the track of the disease, and without it atypical cases would escape notice, especially if they did not manifest jaundice or anaemia. The measure of the enlargement is not necessarily related to the severity of the case; thus "B. Tope," aged 10, is now at school, plays like other children, and has no jaundice, yet has a spleen occupying the greater part of the left side of the abdomen, a fragility of 0.6 to 0.4, and an indirect van den Bergh reaction of 3.1 units. That the spleen plays a dominant part is shown by the complete disappearance of jaundice and anaemia following its removal.

The Anaemia
